Carbon capturing is being attempted in a factory called Carbon Engineering in Squamish, British Columbia. CO₂ is captured from the atmosphere where it is uniformly distributed. So what do they do? They suck in CO₂ from the atmosphere and then clean it up. The gain is new energy fuel. Theoretically, it would be cheap to make because CO₂ is already there in the environment. The fuel thus obtained, the company found, is very high in chemical performance. But it has to be proven to the world which is likely to take time. The fuel is clean, carbon neutral, cheap, free from pollutants and energy efficient. According to the company, the technology is ready and is waiting for the governments to decide on carbon-neutral fuel.⁵² Carbon-neutral fuel is compatible with any human vehicle today. One doesn't need feedstock as CO₂ is taken directly from the atmosphere. So, the company decided to make a carbon-neutral liquid fuel, according to Steve Oldham, chief executive officer (CEO) of Carbon Engineering. The captured CO₂ is combined with hydrogen made through electrolysis of water. The resulting synthetic fuel can be blended or used on its own as gasoline, diesel or jet fuel. . . presto!

Carbon Engineering is pioneering in direct carbon catching. They believe humanity can solve climate change.⁵³ This study on national security believes humanity can resolve energy fears too and pre-empt Olduvai. The pioneering efforts of Carbon Engineering are signs of human capabilities and persistence.

Carbon capture is talked about as humanity's last hope. It is not what this study vouches from the optimism generated. Humans will never lag in energy as long as energy security is handled by governments appropriately. Studies on energy zapping will require calls from corporate energy magnates, scientists, technologists and, above all, governments. The interesting thing about harvesting CO₂ is that it could be captured from anywhere in equal amount. Oldham does not recommend electricity to replace transportation energy needs as it has many constraints compared to carbon-neutral fuel. That makes environment a global commons. It's universal. One doesn't have to run after CO₂ like a lepidopterist after a butterfly with the aerial net.

The process of prospecting energy from CO₂ is continued in other ways too. There are technologies being tested for converting CO₂ into fuel by using solar-powered thin film devices. Metal oxide thin films are fabricated to produce photoelectrochemical cells that can be powered by solar energy. Similarly, there are studies underway to add sunlight to CO₂ to transform it into environmentally friendly syngas (Box 15.3) or methanol for transportation, cooking, energy, heating and so on.

⁵²HBO Now. VICE on HBO. "How CO₂ could be the future." YouTube. https://www.youtube.com/watch?v=Mb_8DJF6Hp0. Accessed 3 October 2020.

⁵³<https://carbonengineering.com/>. Accessed 17 November 2020.

Box 15.3: What Is Syngas?

Syngas is a term for synthetic gas that is a product of coal gasification. It is a fuel gas mixture consisting primarily of hydrogen, carbon monoxide and very often some carbon dioxide. The name comes from its use as intermediates in creating synthetic natural gas and for producing ammonia or methanol. Syngas can be harmful to the environment. Therefore, the syngas product has to be tested to ensure environmental friendliness.

All these experiments though are done primarily to combat climate change, the underlying principle is to harvest energy from spent energy and the ultimate result will be an energy-sufficient sustainable human system. Whether it will match with commercial interests or profit motives will be worth watching. But the fear what will the humans do when the lights go off in the Olduvai style may be out of place if the world dares.

15.10 Governing Energy

Energy is an issue of global governance today. It has to follow the principles of global commons for sustainability even at a national level. There is global control that the nations may feel overpowering. The global energy markets are controlled and governed by the relatively powerful. Most of the acts of war, conflict and militancy are power control through energy manipulation.

Global energy governance needs cooperative energy resolutions at the international level. Such cooperation is imperative for every element of national security even otherwise. It is already late but acceptable, as human systems evolve at a pace that will not be observable for a casual witness. Compared to other elements of national security, energy security may demand a considered and monitored approach to avoid energy deficit and poverty among sections of human systems even within a nation. Energy security is no more a black box. People are aware of the energy games the nations play. This awareness is what will make nations to change their tack in global governance. The twenty-first century world of sapiens⁵⁴ may be readying for that.

The global cooperative governance needs to oversee the issues related to energy resource discovery, exploration, technology, development, movement, allocation and their impact on sustainable development. The 17 goals in the sustainable development programme (Agenda 2030) deal with energy to a great extent. The global cooperative governance of energy needs to be seen externally to the SDGs as a continuing and developing pronouncement. Agenda 2030 is with a fixed end

⁵⁴ Author's considered view of the world today.

objective, whereas energy governance is a matter of human well-being in perpetuity. It needs adoption of a global governance perspective by governments on markets, institutions, agencies, the law and the environment covering all energy resources including nuclear and renewable. Governments have to play major roles in energy security. The quantity and cost of energy are important to governments. This will demand set rules, standards, considerations and international audits by competent and identified agencies in the field of every identified energy resource. There is a need for information systems, transparency and communication in all the dealings; besides, law enforcement at the international level to see unscrupulous players including politicians and militants does not hijack energy market especially in oil, gas and nuclear resources. There should be restrictions in aggressive energy purchasing, hoarding, black marketeering and unscrupulous foraying into producing countries. Counterbalancing the negative approaches of nations in energy markets is necessary for global cooperative energy governance under transparency and geostrategic responsibility.

Global energy governance (GEG) is a critical topic.⁵⁵ It is there but changes frequently. Besides, it is decided by a few selectively in the absence of a universal governance system which is primarily due to the differences among parties and not by the heterogeneous nature of the world populations and nations. One of the reasons is that the global human system is not a system in the absence of a system boundary. Still it is possible to govern energy security in close proximity of global resource governance suggested in this book under resource security. The problem will be the absence of universal human consensus which in any way exists in all human interactions. Overcoming these limitations can lead to many changes in equitable governance of global energy demand. That will also call for an approach under geostrategic security.

15.11 So, What Is Energy Security?

Energy security, in this study, is the seventh identified element of national security in the chronological hierarchy of 16 elements. Energy security, “energysec” in short with the symbol “e_{s1},” is not about saving energy but optimising it for national governance to maximise human well-being sustainably.

Optimising energy means getting the maximum output from the energy the nation has access to and slowly and proactively increasing the availability in a planned manner. An increasing availability of energy is not about saving energy. It is investing energy in energy regeneration programmes and appropriate technologies. It is a high-value mega governance task. It is for the government to execute. Energy fatigue can make nations go weary and crazy. This can be analysed by observing the

⁵⁵ Van de Graaf, T., Colgan, J. “Global energy governance: a review and research agenda.” *Palgrave Commun* 2, 15047 (2016). <https://doi.org/10.1057/palcomms.2015.47>.

behaviours of nations at specific times and critical situations including the conflict mindset of governments and tendencies of power abuse among authorities.

In this study, energy security is an element of national security. Accordingly, energy security needs to be seen integral to national security inclusively with other elements. Energy security in almost all its definitions is associated with national security and availability of natural resources for energy requirements of a nation. Therefore, there are chances that energy security may shift or mix up unknowingly to resource security. It is a common mistake governments and experts commit. It is important to understand managing energy resources is different from managing energy in national governance, though both of them are interlinked, and so are other elements of national security. This fact has to be made clear to decision-makers. The problem is that energy as a resource becomes a commodity that can be expensive, economically competitive, denied or under conflict depending on the global power shift. Energy distribution needs to be balanced evenly within a country. Uneven distribution of energy from the resource point of view has led to significant vulnerabilities among countries.

Regeneration of energy from dissipated energy is a subject that holds some potential for the generations to exploit. That promises energy sustainability. The author believes it could not be left unattended as humans have reached to the intellectual level to experiment with such concepts based on the conservation laws originating from physics and in the study of space-time. The space-time manifold is four dimensional but in a singular form relativistically. If it doesn't change in time, then energy is conserved. If it doesn't change in space, then momentum is conserved. Within this theory, somewhere remains the human quest for perpetual energy for sustainable quality life. It may sound philosophical at the moment. That is why one needs to hang on to philosophy—to preserve intellectual survivability till the argument could be put forward in an applicable manner.

Global energy governance is a modern subject. There was much talk about international energy cooperation. The concerns naturally focus on immediate market scenario for short-run prospectus. It demands long-term prospective. It doesn't mean nations have to sacrifice their advantages. A win-win scenario is what they should look for their own requirements of energy security and associated advantages in changing times.

15.11.1 Definition: Energy Security

Against the background of this study, energy security means “*the capability of a nation to generate, exploit and sustainably optimise energy for maximising the well-being of its people by governance, perfectly aligned with the other elements of national security and integrated with all the terrains of national governance.*”

15.12 Summation

Energy security is a defining policy issue for any government keen on the well-being of people. Secure, stable, economic and sustainable energy supply on demand is the key for energy security. It is an international issue and specific to geostrategy of a nation under the ever-changing energy scenario. The general concern is more on retaining energy than maximising energy security. Besides, energy security has been habitually considered to be a zero-sum game among nations. There are hungry and devastatingly irate energy guzzlers in the world among nations. It is amazing how insecure they are!

A government should learn not to pre-empt energy slip when the demand for energy peaks. Energy security is not as per the wants of the people, but that of the needs of a nation for maintaining and moving forward in national security. Energy security has never peaked or headed to a dead end since fire appeared in human social system as in recent times. Fire entered the scene long ago. It was the first good thing that happened to a helpless biped called *Homo sapiens*. Today, the biped is talking of zapping it from spent energy. That itself is an indication that humans will never run out of energy to meet the needs where needs need to be defined precisely. That is the first step in national governance. There are no other solutions such as saving energy and so on. Frugality is actually not necessary in any situation of human life. But governing waste to zero is an utmost essentiality for good quality life. The need for energy is based on a nation's strategic national security appreciation. Humans will reach their crowning glory in energy security when they learn to zap energy from spent energy to govern energy sap.

It is for the nations to manage as an element in tandem with other elements. It is a decision problem for the governments. The world doesn't have to struggle for energy security as it has been made to believe. "Energy can neither be created nor destroyed"; if true, the answer for energising the future lies in this statement.

16.1 Introduction

Geostrategy is a strategic term in national security governance dealing with international understanding and relations in the national and global perspective. As an element of national security, geostrategic security is about a nation's choice of existence among other nations geostrategically: adaptation to world normals, foreign policy intervention, streaming geopolitical objectives (local, regional and global), conflict resolution and guiding the principles of national policy, all aimed at maximising national security. Geostrategy is not diplomacy, but without diplomacy, geostrategy cannot be formulated and executed successfully. It is a long-term action plan that will keep shifting but all the time pointed at the end objective, the goal—

geostrategic security. Every citizen can cause an impact on the nation's geostrategy. A country can hold itself internationally through its citizens.

Geostrategists may consider the overall stasis of the nation throughout the period it has been in existence as a continuum in relation to other nations while planning geostrategy. When a country is abhorrently disliked, odiously hated, vehemently suspected or sarcastically castigated by the citizens of its neighbouring and faraway countries, it could be frenetically incongruent lacking in geostrategic security—an essential ingredient for healthy endurance of a nation and its people in the world of nations even if it has traces of retarded geopolitical envy and jealousy. Nations behave similar to individuals in a human system. A nation is organic and macro individualistic.¹ People alone make or break them. Individual and group behaviour patterns are extendable to nations too. External forces are contributory, however strong they are felt. The weaker a nation feels under external pressure, the lesser is its geostrategic security for survival. A nation should understand it. It has to look inward for reasons. Every nation that has remained endangered and finally destroyed and vanished from the map was imploding from within for long periods of time. The maps of the world change over periods.

National governance and the state of nations are subjects of constant attention and discussions. The endurance and sustainability of a nation are not strictly in accordance with its power status (political and faith based), but the way it governs its geostrategic security. Many nations without any substantial power in the company of others survive breathing simple geostrategy. The reason for their survival in a world full of nations is embedded in their geostrategic capabilities. Geostrategy has to tick continuously, like the heart, for a nation to survive assiduously among others.

Power games and associated behaviours are common to primates. But in the game plans of human species, abhorrence is a key behaviour when a nation muscles its way through international aggrandisement to retain its position of power or obtain it by whatever means. Every means is justified and rationalised. Nations that felt insecure invaded others or established colonialism for exploitation. Their empires collapsed subsequently under abhorrence and induced responses. The scenario is applicable to the positions of many nations today and can be examined as case studies. It is one of the biomodels that the world needs to consider seriously while determining geostrategy.

India is an example of how geostrategy security governance can turn around cynicisms gathering advantage of gratifications. India's geostrategic position was said to have been weak in the past, especially with respect to its neighbourhood diplomacy. In Nepal, it was said to hurt their national pride. Bangladesh Rifles invaded Indian borders and massacred villagers and the Border Security Force (BSF) personnel. The general election in Bangladesh was fought with anti-India slogans. Hate came in different forms. There were strong anti-India sentiments in Bangladesh

¹ Individual behaviour amplified to a group level.

behind political decisions.² There was no warmth in relations in spite of the fact that India created the country for its people. It was a new country born out of a war fought by Indian blood—a war that gave no benefit to India except a face-lift and existential poise. Bangladesh remained ungrateful and that was what it was going to be in future too, observers stated.³ There was a lot of simmering suspicion about India in Bangladesh under subversive situations. In fact, there was more warmth between India and China who fought a disastrous war in 1962 than between India and Bangladesh at one time. Both the governments and the opposition in Bangladesh were competing to put blame on India for everything that happens there and at the same time internally trying to woo it.⁴ India was blamed for everything that went wrong in Bangladesh. Perhaps, the only area where India was excluded in blame throwing was in the damages caused by frequent cyclones in Bangladesh (in spite of the fact the cyclone deflects from India before hitting its favourite niches in Bangladesh!). The hate allows Bangladesh to be sympathetic with anti-Indian insurgents across the border in the northeastern part of India and behaves with fury at the border. There are reports that Bangladesh openly supported anti-Indian insurgency as well as militant activism providing sanctuaries close to India's borders. Countries that had scores to settle with India get generous support from Bangladesh. In such international hate campaigns, the loss was more to the bigger country than the smaller one.

Things have changed since then as it happens in international relations linked with geopolitics. Sheikh Hasina, the prime minister of Bangladesh, visited India in October 2019 as most of the issues between the two countries were resolved by then. It was a positive step in the relationship between the two countries.

In Sri Lanka, Indian Peace Keeping Force (IPKF) had to withdraw wounded and humiliated after losing a thousand soldiers evoking serious bitterness in relations, all by failed geostrategy. Historically, India and Sri Lanka hold a strong bond and it is not easy to break it, the two nations realise, in spite of many interventions and skirmishes. The relations improved gradually through various interactions. Trade and investments in development, education, culture, defence and nuclear deals have grown. There are various developmental assistances by India to the internally displaced persons (IDP) and other disadvantaged sections of the population of Sri Lanka.

In Fiji Islands, an archipelago comprising 332 islands, Indian settlers (about 38 percent of the population) were castigated when the native Fijian Lieutenant Colonel Sitivieni Rabuka overthrew the elected government that comprised the majority Indian-Fijians in a military coup in 1987 with the declared intention of preserving *Taukei* rights to the native Fijians who felt endangered. Owning land, etc.

²Mustafa, S. "Hate-India Movement in Bangladesh." *The Asian Age*, New Delhi. 26 August 2004, pp.1–2.

³The scenario is changed today. Bangladesh and India stay committed for sustainable development by mutual cooperation and trust (2021). Trust is the key in geostrategy.

⁴Ibid.

by non-natives are issues unless the constitution is amended. The relations became sour after Rebuka's coup.

But things changed subsequently and relations improved. India never isolated the country but instead worked with the government. At the second summit of the Pacific Islands countries, held in Jaipur in August 2015, India announced plans to open a space research and satellite monitoring station in Fiji. The station will enable India the capability to track satellites independently. India previously relied on the United States and Australia to assist it with monitoring its satellites over the Pacific. India has signed development cooperation with Fiji on various issues including developing sugar industry and their diversification for biofuel production.

In Malaysia, Indian nationals were kicked and their passports were defaced by the police in a sweep against illegal immigrants in March 2003. 270 Indians were rounded up and ill-treated in the Indian-dominated Brickfields in central Kuala Lumpur. They had visas. Still, they were forced to apply for fresh visas.

India's relations with Malaysia seesaws under changing situations based on issues. There are historical relationships between India and Malaysia. The ties leading to antiquity often smothers when situations go out of control. But the relations trended downward under the octogenarian prime minister of Malaysia Mahathir Bin Mohamad in spite of his Indian ancestry. The situations reversed when a new government came to power in Malaysia.

In the neighbouring Singapore, there were many Indian labourers who were not permitted to visit tourist spots around the country. They were virtual prisoners with territorial limitations. These labourers often said to end up as petty thieves and create nuisance in the public when let loose. But such situations are often left as the prerogative of the host country rather than issues for finding fault. The relations between India and Singapore have been traditionally strong and enduring. There are agreements between the countries to increase trade, investments and economic cooperation besides maritime cooperation, counter militancy, technology and naval cooperation.

In France, a friend explained how Indians were stalked in supermarkets to see that they would not lift anything from the shop windows. The French was wary of Indians considered kleptomaniacs. In London, there was general hate against Indians, Pakistanis and Bangladeshis, who according to the native Brits swarm the country in search of opportunities—colonisation on the reverse. In Persian Gulf countries, Indians were seen from religious angles of priority, though still as second-rate commodity employees. All these are common in international relations especially when there are demographic, economic and other differences and the purpose for which one observes the other through the prism of international relations. The India centric explanation is as an example, though every nation has its own geostrategic signature. Humans are born into the planet; then, they made it into a dormitory of sorts if not a hospital ward.

The people of Pakistan have a love-hate relationship with India. The hate originated from the love that bonded them for years but coagulated badly by rising religious sentiments mainly external to both the countries kept alive by vested socio-political interests of the powerful. India would lose more in this game being a larger

country with a higher population and secular in nature where threats to religious feelings could fray and tear the fabric. The divide was the one that originated when a close-knit family split one day. It was more forceful than any other separation that could be mended by time. This one would not. The reason is the polarity of the world which is absolute. The twiddling games would go on endlessly. Following such split among nations, rumours and deliberate distortion of histories had taken place. There will be cultivated ignorance that will bar togetherness.

China, a nation of great traditions, though short in continuum,⁵ was ironically a victim of its own traditional psychology deep rooted in suspicion and deception. It was doubtful whether China would ever get close to India with absolute confidence in India's sincerity in human relations across the world, in spite of the fact that history was evident on it. It would be difficult for China to mend its relations with Japan, how much the latter may apologise for the so-called crimes of war as then Prime Minister Junichiro Koizumi did openly in the Afro-Asian summit at Jakarta in 2005, because the geostrategic personalities of China and Japan were different like in the case of many other nations. Nations are simply different from each other, like individuals within the singularity and differentiability conundrum. That is why the world is more of a hospital ward than a dormitory. That makes the concept of global security a far distant dream. The secret of geostrategy lies within this difference. It demands advanced sapient human attitudes towards another. Run-of-the-mill approaches in geostrategy even if tested in history may not be sufficient when history itself is changing. Under such predicaments, a nation has to choose a path that has never been taken before. Such paths are available. But humans feel comfortable treading familiar paths. There is an aversion towards the unknown and untested. The reason—nations are in a hurry. Geostrategic security calls for patience and preservation. This is where even the truth in a biomodel will not find credibility in a situation where conditioned traditional belief system overrules reality expressions. The war in 1962 between India and China originated from such a situation. India never had the intention to be aggressive with China. India's geopolitical failure amplifies in its inability to see the world through the eyes of the world. It is the general mistake any nation makes in geostrategy. That will also shackle a nation in its process to superstatedom (Box 16.1). China felt India deceived it. Its psyche is conditioned. There is a kind of distorted sibling rivalry between India and China with a concealed edge of paranoia and distrust. It is evident in China's closeness with Pakistan. India's relationship with China is also fuelled by the fear the United States has about China's race to overtake. A sound containment system, therefore, is the prerogative of the United States. After all, the United States is the containment expert of the world. Under these circumstances, India may find China a strange bedfellow in all its dealings in geostrategy.

Through this smog of hate, misunderstandings and deception, and with all its internal problems, India moves with Zen like calm; that is another matter. The problem is also one of perception. And that is the biggest taboo in geostrategic

⁵ Assuming present continuum stasis since 1949 with the turnaround under communist regime.

security. Does hatred mean the adopted geostrategy is weak? After all, there are many countries that admire and love India, in awe with China, listen to Japan and hail the United States and thrive. At the same time, according to media musings, there is a feeling among the neighbours that India does not help them. Perhaps, India doesn't have this capability according to their perception. Instead, it treats its neighbours like monopoly markets.⁶ But there are visible changes.

Box 16.1: So, What Is the Idea of Superstate?

Superstate is a finding of this study. It is a non-utopian concept of a nation whose national security index (NSI) is above a benchmark established and periodically reviewed by a world authority of collective nations under absolute *consensus ad idem*. To establish the idea, the global human system will have to first accept the concept of national security as per this study and agree collectively to identify the metrics for precisely assessing the NSI. The people of the superstate are expected to experience maximum possible well-being under a successful governance by national security (GBNS) and thereby feel responsible for collective well-being of the global human system. It is possible.

The idea of superstate may offer opportunities for the world to shift from the present binary bipolar global system controlled and balanced by the power of politics and faith to a matrix system ideated by the superstates and not superpowers. A superpower need not be a superstate, but a superstate will have the power to control and contain a superpower and itself within the matrix. This is a take-off from note 118, Chap. 2.

In the meantime, the idea of superstate may provide direction for governance to nations that consider it as their objective. It is their choice, but the earlier the better.

Look at India's position again from a different perspective. Geographically, it is unique not only by its location but also by practice and cultural identity. It never invaded another country in military history according to the true sense and purpose of it. It is an interesting finding to understand the psyche of a nation. Aggression was never India's forte. India accepted faith systems with open arms, besides retaining strongly the original human thought and behaviour process with unswerving choices to suit every human in the quest for spiritual security. Its neighbours are varied. It believes in tolerance and peaceful coexistence and though may not have succeeded in conveying it to others. People are secular and extremely hospitable, though mannerism may not be appealing to others in affluent countries with much less

⁶Trikha, S. "I am Ok, You are Not OK." *The India Express* (Mumbai), 10 June 2001, Section II, p. 1.

population.⁷ One-fifth of the world's population is in India. And the share is going to be more in the future if the continuum keeps on. India stands to gain highly in geostrategic advantage, if it learns to manage its population productively for maximising national security. India's power centre is its people, provided they are utilised positively and invested wisely. It is also true for every nation. That is the crux of geostrategy.

16.2 Geostrategic Security: Setting

The world was never insular and will never be, though some of the countries were labeled that way. All of them have people as part of the global human system who may behave in different modes and patterns. The world was generally reaching out from ancient times. It is evident from the “journey of humans” or the sapien trail since the early days. Migration and peripatetic movements are inherent in human system. That's why this study is adamant that the entire planet belongs to everybody. It will take time, lot of it. While arrested humans merge with their minimum system environment, static humans are limited by area. They are limitedly dynamic within their territories. Dynamic humans trespass the territories of others, sometimes claiming them. It is from this principle and historic biomodels the conclusion that the world will always remain global and not insular is arrived at. Insularism is against human nature even in arrested or static survival systems. One can see this in the host–guest interactive behaviour among people of all kind. The world was truly global *ab initio*. It was accessibility that was limited. People knew about others. Human systems were engaged in geostrategic interactions from the beginning of history. Geostrategy, therefore, is not a new word. It is geostrategy that provides a geopolitical entity the necessary comfort and permanence in its existence in the world full of nations. It also provides bargaining power and the requisite clout within them without being abhorrently despised. Power can come even otherwise. But it need not provide comfort to the citizens if not by positive and proactive geostrategy. Against this background, geostrategic security, as an element of national security, has to be perceived as a nation's capability to remain healthy among other nations in a world of nations in such a way that its values and citizens are acceptable to the world along with its existence.

Geostrategic security is a vastly transforming element of national security. A small twist or an abrupt turn can lead to a massive change in international relations. The socio-political scenario is a major change driver as humans have become anxiously dynamic. Within the shifting power scenario, a well-crafted geostrategy

⁷Majumdar, A. “‘Melting pot or a patchwork fabric’: Ten lies on India's culture of co-existence that latest Pew survey has busted.” <https://www.firstpost.com/india/religious-tolerance-in-india-10-lies-on-indias-culture-of-co-existence-that-latest-pew-survey-has-busted-9777801.html>. Accessed 5 July 2021.

can support the desired survival requirements of geopolitical entities to endure and establish their socio-political presence in the international system. Geostrategy helps a nation to merge its geopolitical outlook with strategic considerations. The question in geostrategy is whether a nation has to focus on its own existence without consideration to the existence of others or collectively on the existence of all. In other words, is it “unitary survival at any cost” or “survival with all” in a world full of nations? The answer depends on the outlook, whether geostrategy is used in the national context or global context.

Geostrategy as a subject is as old as Herodotus’ *The Histories* (seen earlier) which in most parts has been criticised for fanciful statements. Interestingly, predictions in geostrategy have never been proved right. The idea that geostrategy is influenced highly by geography, development of nations, larger states devouring the smaller ones like in a food chain, rising and falling of great powers, unification of erstwhile powers, organic theory of state... everything had its abruptness in continuity. Geostrategy did not fail its initiators and forecasters. It was time and system entropy that influenced predictions. The forecasters did not identify the influence time and system entropy incorporate over a prediction in geostrategic appreciation. Time doesn’t change, but it changes everything else through his companion, the entropy. Simply put geostrategy is not a predictive tool but a strategic plan based on a desired objective with an achievable goal.

Geostrategy as a subject has been heavily criticised as a kind of hype sans human will and approach leading to indeterminate aggression of human systems under expansionism without compassion. That obviously won’t sell in the evolving world. Geostrategic security recommended here is different from the geostrategic approaches so far.

16.3 Examining Geostrategic Attempts in Statecraft

It is necessary to know that geostrategy according to this study is considered a fairly modern concept and recommended for practising under a win-win situation for the future. It is not necessary that the ideas constructed under such scenario should be acceptable to all the “beneficiaries.” It is the results that matter. The conditional exclusion of individuals and replacement by groups in government is the theory behind winning geostrategy. Vested individual interests, political, economical or setting sights on power, defeat the modern idea of geostrategy where collective winning is the only choice. This could be termed idealistic. Yes, it is, for now. But the time is ripe to make it idealistically realistic and then realistic at a later stage. The beneficiaries should know the benefits before any ideology becomes acceptable. In winning geostrategy, the competition is not between governments, but the achievable results and governments. The game is to expand and exceed the results ideated earlier. Bilateral, regional or global scenario will form the background. It is difficult to say which will offer more productive situations. It depends upon the relationship

of a nation with the chosen ones at the start point of geostrategy according to the scenario.

Statecraft is the art of leading a country. The idea is quite old. A country needs to be governed, not led. Leadership is one of the skills that an individual should possess in the overall governance set up.⁸ But the term leadership is still valued greatly in critical geopolitics, which is still individual oriented. Overall national security governance looks at governments to govern, not an individual leader to lead. Leaders are important situationally. Governance is much larger. Leaders are expected to lead at every level of the organisational structure and hierarchy designed for governance including at the helm of affairs of the nation. National security maximisation is not attributable to individuals, but the groups associated with governance. In this argument, there is a deviation from the earlier thought process of critical geopolitics. Critical geopolitics engages in geopolitical discourses, practices and history of geopolitics through critical discourses. Critical geopolitics, accordingly, argued on various issues including international competition, resource allocation, energy pricing, energy utilisation, strategic and political sanctions, rogue behaviour of states, terrorism, trade, covert and subversive operations of the third kind, transboundary matters, crimes³⁺, nuclear clarifications, geopolitical weapons of war. . . the list is exhaustive.

Statecraft has been the underpinning policy in gaming geopolitical escapades and attempts for gaining ground in power balancing for nations. Geostrategy remained a part of statecraft. Geostrategic attempts in geopolitics as part of statecraft, therefore, matter while considering geostrategy in its new avatar according to this study as an element of national security in forward thinking.

There were many geostrategic attempts in statecraft in the past. It included formation of nations and union of nations, collaborations, movements, treaty organisations and so on. There were also unity slogans. Some of them attained diverse perceptions. One such slogan was the often-quoted *Panchsheel* in Sino-India relations. Most of the Indians fancy *Panchsheel* as a Sanskrit word coined by Jawaharlal Nehru (1889–1964), the first prime minister of India. In reality, it is an Indonesian usage formulated by Nehru's Chinese compatriot Zhou Enlai (1898–1976). Nehru, according to reports, was responsible for propagating its principles.⁹ Nehru and Zhou Enlai issued a joint statement in New Delhi on 18 June 1954. While receiving the Indian delegation to the Tibetan trade talks on 31 December 1953, Zhou

⁸Paleri, P. (2018). *Human investment management: raise the level by capitalising human*. Springer Nature Singapore Pte Ltd. p.

⁹Paranjpe, V.V. "Panchsheel: The Untold Story." *Hindustan Times* (New Delhi), 18 June 2004, p. 10. The *Panchsheel* was conceptualised to be the basis of friendly relations between India and China. But it became null in the wake of the 1962 Sino-Indian War. Under the agreement, India gave up all extra-territorial rights and privileges it enjoyed in Tibet. India formally recognised Tibet as a region of China. The name (*Panchsheel*) derived from the five principles that were agreed upon. They were (1) mutual respect for each other's territorial integrity and sovereignty, (2) mutual non-aggression, (3) mutual non-interference in internal affairs, (4) equal and mutual benefit working relationship and (5) peaceful coexistence.

enunciated the five principles governing China's relations with foreign countries. This was to become the famous *Panchsheel* later when Nehru appreciated the principles.¹⁰ But there was resistance from China including it in the text of the India–China joint statement. With various compromise solutions, the slogan destined to be an impossible dream appeared in the preamble and not in the main text.

These incidents may show an interesting face of geostrategic principles in statecraft—historic agreements can be distorted and disregarded; the real power may lie with someone else, not the one who projects power outside. While Zhou Enlai was the head of government and an efficient and effable face of China to the outside world, the real power was with Mao Zedong.¹¹ Whereas in India, Nehru sat in the centre with lights focused on him. Behaviours of world leaders and power centres can take exactly the street behaviour and remain dormant for years. There are leaders who believe there is little room for peaceful coexistence, equality or common good and primacy of law, all within the system that calls for it. Mao clipped the wings of *Panchsheel*, little known to Nehru (an assumption). The deceptive Chinese attack on India in 1962¹² was not the doing of Zhou, but of Mao as some analysts state.¹³ In history, people can get tainted or become heroes without reasons. History may warp reality. It was said before.

Deception is habitually practised and widely advocated not only in war but also in geostrategy under statecraft. Aids and support coming for victims of disasters may involve opportunities that the good humanitarian donour may put to advantage. There are many such projections. More could be identified by serious research. A nation has to watch for them carefully and patiently in geostrategy to understand itself. The next step is to understand the other. Understanding the other is relatively easy. In geostrategy, what is difficult is to understand oneself. Often it could be an inflated visualisation or outright disgust, not a reality perception.

The importance of deception in geostrategy is highly debatable. It is generally acceptable to all from historical times. The Chinese strategists believed in it. Sun Tzu, projected as the author of *Art of War*, was an advocator of deception. The Japanese engaged the United States in peaceful negotiations at Tokyo while preparing the attack on the US naval fleet according to historical records. It formed the background of the very successful attack on Pearl Harbour.¹⁴ Deception, tactical or strategic, misleads the enemy in war. It means there is an enemy when deception is

¹⁰Ibid.

¹¹Ibid.

¹²The time of war was during the Cuban missile crisis. Was it an attempt to enter early in a world war by China? Why did they walk away from Manipur? There are many questions and associated blame throwing on this war which was not analysed properly to find the truth from facts.

¹³Paranjpe, V.V. "Panchsheel: The Untold Story." *Hindustan Times*, New Delhi, 18 June 2004, p. 10.

¹⁴Is there a similarity in the Pearl Harbour attack and the 11 September 2001 terrorist attacks including the consequences of the attacks? Deception was a common factor in both the attacks. There are indicators that deception could not be rewarding in the long run. On the contrary, it could be very damaging. The United States was not a superpower during the Pearl Harbour attack. It also

used. Or the deception that one engages in is aimed at an enemy. But is there an enemy when a government crafts its geostrategy?

There are many such similarities where, between peace talks, one party was preparing to attack the other or trying to reorganise its position in a conflict. The induced deception in peace talks has made many such talks being viewed suspiciously by nations. It happens with India. It was one such peace attempts that allegedly provided cover for Pakistan in planning its attack on India on the line of control (LOC) in Kargil in 1999.¹⁵ What was interesting in this deception was that even the Pakistani democratic political establishment was held hostage by the military. The democratically elected government of Pakistan, as subsequent events pointed out, was not aware of the intentions of the select military echelons at the top.¹⁶

In international relations, deception stems from the inherent lack of faith in each other. It is necessitated by the “win at any cost” strategy—“the end justifies the means” argument—that most of the nations adopt under such circumstances. The lack of faith in each other is integral to geostrategic dimension and is the most intricate impediment in mutually supportive coexistence of nations. Deception ingrains lack of confidence. Confidence building measures (CBM) will not be effective under conditions of deception and suspicion. Deception is the accepted and practiced norm of winning over another. It is clearly mentioned in all treatises on ancient and modern arts of war. Covert operations are based on deception. With all these in position, can deception be accepted as a normal geostrategic tool? It needs to be analysed further. It was deception that was behind the famous visit of Henry Kissinger to Pakistan through India to establish relations with China in July 1971.¹⁷ India was not aware of Kissinger’s real mission—to slip away to China through Pakistan for talks. India misunderstood that Kissinger would resolve its issues with Pakistan regarding the turmoil in East Pakistan¹⁸ and subsequent refugee problems. Only a few, including the Pakistani leadership, knew about the plan. It caused much heartburn to India and serious flaws in Indo-US relations thereafter.¹⁹ Kissinger by

showed that deception backlash could be very serious to the perpetrator. In geostrategy, it is a serious matter.

¹⁵ The Pakistani attack along the line of control (LOC) in Kargil was a surprise for India and perhaps a reckoning that deception in every which form is a reality in international relations. According to the Committee appointed by the Government of India who reported on the war that lasted from May to July 1999, “Pakistan chose its ground with treacherous cunning, even as India was being feted with an olive branch and promise of a negotiated peace that climaxed February’s (1999) famous bus ride to Lahore.”

¹⁶ In a brilliantly orchestrated coup d’état, the military commander Pervez Musharraf dismissed the democratically elected government on 12 October 1999. The prime minister of Pakistan Mian Muhammad Nawaz Sharif was arrested by the military and exiled to the Kingdom of Saudi Arabia.

¹⁸ East Pakistan subsequently broke away from Pakistan as a result of a war between India and Pakistan (1971) and became Bangladesh, a separate nation.

¹⁹ Ibid.

his deceptive diplomacy caused much damage to India–US relations that still linger as a hangover. That is a bad diplomacy. There are reports that Kissinger and Nixon had virtually abandoned their gentlemen status, that too of a superpower country, while expressing their feelings about India and its then prime minister Indira Gandhi. Even the chief of the worst cartels of the underground in the United States may have been many shades better than these two power brokers of the period. It is also amazing that Kissinger with such deprived wisdom had the audacity to author a book on diplomacy.²⁰ That is another reason for arguing diplomacy need not be mistaken for geostrategy.²¹ It is a tool.

In the normal case, theoretically, when deception is accepted as a tactical ploy, a war is won even if battles are lost. An example is the epic Trojan War. But if ruled out as a mythopoeian farce,²² there are no strong examples of the deceptor winning at the ultimate end. It can be seen in the Pearl Harbour attack or in the Yom Kippur War. More obvious is in the acts of terror. Terrorists never win, because they fight under deception. They do not know it. Deception does not succeed beyond a momentary replenishment of hope to the deceiver. Hence, geostrategy sans deception is strictly the best method that can be approached in the long term under the evolving times of heightened globalisation and cross-border interaction. Confidence measures are part of this strategy. Unless deception in its every which form is taken out, long-term geostrategic policies will not find ground especially in a world that will remain turbulent by human behavioural vicissitudes. Geostrategic game plan is to create win-win situations, because that alone will maximise geostrategic security. Often, the real motive lies submerged in the original thinking. Geostrategy with an intention to subvert or suppress has not registered much success in historic biomodels. Ultimately, deception gets deceived. Geostrategy is group survival. A large number of nations have lost out on it.

16.4 Diplomacy and Geostrategy

A lot is spoken and written about diplomacy by experts, who have a feel for it. That includes heads of states to professional diplomats, travellers to armchair strategists and media personnel to casual readers. But in geostrategy, diplomacy is just a tool, and a sharp tool it is. Sometimes, diplomacy is also conveniently branded as an instrument of national policy. But in its real sense, it is the package in which national policies are projected to the outside world. If that is so, then diplomacy is the

²⁰Kissinger, H. (1994). *Diplomacy*. Simon & Schuster.

²¹Of course, there is a critical comment on this book in which a reviewer had commented, “This book unfortunately has a misleading title, as it is much more about history than about diplomacy itself. But that is not necessarily a problem, as it still has a lot to offer.” https://books.google.co.in/books/about/Diplomacy.html?id=VPHQMG3Ue1wC&redir_esc=y. Accessed 23 May 2020.

²²Truth in fantasy.

responsibility of all those who are engaged in projecting national policies across a nation's borders. It is very much an essential part of a nation's geostrategy.

While career diplomats and those who are assigned specific diplomatic duties are formal representatives of a country abroad, matters related to geostrategic security of a nation has to be worked out by those in the strategic business and thereafter formulated into policies by those at the helm of affairs in the political establishments. It is this strategy that is executed by diplomats whether career diplomat or otherwise. Engaging the people of a nation in the business of geostrategy through information is an activity that relates to diplomacy building and enhancement. To that extent, even an unfortunate hostage or a strayed off infiltrator will have a message to convey to the world if geostrategy is made interactive with the common person. It will take away the awe and conditioned xenophobic attributes from a citizen with an awareness that will induce geostrategic awakening. Diplomacy is not just the forte of the foreign office. It will do better for them to unleash the power of the ambassadors by situation—the cross-border travelling citizens. Geostrategy lies in the clarion call about the external world to a nation's citizens that they can use for their country's benefit from a mutually beneficial point of view with respect to the countries of their visit. Unfortunately, the common person is kept totally away from the nation's geostrategic business. Active foreign policy is when the citizens know their roles in maximising the geostrategic security of their nation—diplomacy is the track on which that works. The tracks are not different for the ordinary citizen or the appointed diplomat in this regard. Diplomacy becomes a casualty when it takes different routes beyond what is normally depicted as official and unofficial routes. For the uninitiated, the over-ambitious or the wheeler-dealer in geostrategic diplomacy, these pathways are called track one and track two, where the latter is outside the government activities in diplomacy that they expect the government to recognise by gathering strength. Unfortunately, both the tracks diverge uncompromisingly. Track two is a costly waste in geostrategy, though for the parties involved, such efforts bring fringe benefits. It is also a sign of flaws in official diplomacy. In both ways, geostrategic security is the loser. At the same time, it is not expected out of responsible citizens of a country to neglect their part in diplomacy in the modern world. Therefore, in an ideal situation, both the tracks shall converge and assimilate into each other. This will bring single-track diplomacy (that may have different choices), ideal for geostrategic security maximisation. An opposing view of the citizens, if any, in such cases is not track two but counter diplomacy which is extremely harmful to geostrategic security maximisation and a breeding ground for geostrategic deficit. The government has to be watchful about such developments. Such attempts gain considerable advantage to their promoters with huge funding and recognition.

The power of the common person can be seen in the “diplomatic” engagement by the insurgents and militants. These groups engage the common person effectively. Coercion is not involved mostly. A major source of income for an insurgent group in South Asia is the contributions from the non-resident citizens. The income besides being huge is assured for the cause. While the method used by such organisations may not be advisable to a government, it could effectively utilise even a casual

visitor abroad for a better geostrategy at least for confidence building among population. The foreign office should not be acting in isolation. But it may. This aspect, the common person diplomacy or hoi polloi diplomacy, is not in the agenda of any nation's diplomatic moves.

Diplomacy is a relationship. The textbooks classify as passive, gun boat, dollar, controlled under pacification, public and so on. This study adds another term—hoi polloi diplomacy, in which the common native supports the nation in geostrategic security governance.

16.5 Is There a Hierarchy of Nations?

In the beginning, it has been mentioned that this study looks at human systems as a unitary civilisation, where civilisation is human system advancement as an intellectual evolutionary process considered as a whole and not in parts. This is under the assumption and acceptance that humans use intellect as a survival tool. It refuses to see people on the planet as belonging to different alcoves or pockets called civilisations while studying governance under the concept of national security towards human well-being. The study of national security, though exclusive to national governance, needs to look at the planet as the ultimate human system within the singularity and differentiability of human beings. For this purpose, the planet can be visualised as a marble jar or by any other metaphor that can identify with human systems within human systems and collectively together within a global system boundary. But national security concept is only applicable to nation systems and not the global system as it needs a clear definition of a system of governance for application. In a global system mode, humans belong to a unitary civilisation. The clashes are not between civilisations but within the unitary civilisation similar to the thunder, lightning and pressure variation in a highly turbulent vertical column of cumulonimbus (C_b) cloud in varying diameters. That is what the human system is according to the author. The vertical C_b is replaced by a horizontal worm tunnel, equally turbulent as in a C_b cloud, where humans move forward in a kind of ant column. But unlike it, the individual humans stand longitudinally separated by intellectual differentiation of awareness, the quantum of which is yet to be identified for defining. The fact is that people are placed in a hierarchical position, one behind the other in the worm tunnel of unitary civilisation. The tunnel extends forward as humans advance in intellectual evolution. Interesting fact is that the humans are also placed transversely as if in an exclusive lane for each individual similar to a running rack in such a way there is no obstruction for one to overtake another or fall back in individual hierarchy. The hierarchical line up of people, one behind and ahead the other, keeps happening all the time. The human worm tunnel is a subject that will call for extensive study. No one blocks anyone and no one is similar or equal to another at any time. This gives a relative feeling of hierarchy.

It is the same humans that form the human system as individual marbles in relative expression. The nations are marbles with many human systems formal and

informal within. Hence, they cannot be compared with the individual human hierarchy in the worm tunnel. They can be considered as the marbles in the marble jar mentioned earlier as national systems. They are yet to become a wholly collective single marble jar globally. It is not likely to happen at any time in the near future due to human limitations. They are in a different character frame wherein one vanishes, micronises or macronises. New nations will join at intervals as another marble in the combo in the global combo of jars. This is where the concept of hierarchy of nations is introduced as they are also human systems that behave as individual entities. This hierarchy, which is hypothetical with a probable positive appreciation, is what is mentioned in this section as hierarchy of nations. Is it there already?

Not exactly, but it is possible to define nations hierarchically based on their respective NSI of well-being. It is not based on power whether hard or soft²³ associates but by the NSI of well-being and associated power that will be more than that of exclusive military power. The global hierarchy of nations, according to the power they can wield in the community of nations and the capability to hold on to that power from falling, is one of the perceptions. In reality, it does not exist in a form that is intentionally legislated or accepted. But in any form of human society, there exists a system by which one is compared with another. This is an approach that is highlighted here.

The hypothetical hierarchy may not be in the form of a pyramid since the number of countries in various categories may not shape a geometrical pyramid. Besides, it is based on the power the nation wields in geostrategy. Can there be two nations with equal power in the hierarchy of world systems? Does the power shift with respect to geostrategic situations? These and similar questions need to be examined before designing the shape of the hierarchy of nations. Ideally, the probability of two nations of equal bargaining power is very less. Power varies. Assuming each nation wields different degrees of power, the shape of the chain of nations of the world in the power hierarchy will be that of a train as a function of time—with one nation following another in the configuration of railroad coaches. Even that does not suit the expression, because in such a chain, a nation will always follow the preceding one, whereas in real mode, it may overtake another. The coach of a train does not move that way. The shape of the hierarchy could well be that of an ant column on the move with one following another with the freedom to overtake. Or does it look like an overcrowded footpath where everyone is on the move in a busy city? They all manage it well without physically touching the other whether Times Square in New York, Churchgate in Mumbai or Shibuya in Tokyo. Even pickpockets in the crowd only touch the pockets before vanishing into thin air. The shape can change with respect to the situation. But it has an apex if the shape is that of a pyramid or a head at the beginning of the long winding entity, though the system may not be very shapely. The head of the entity has to be the superpower or whatever it is called.

²³This study does not recognise the term soft power and associated theory for comparison. Military power is recognised based on the element of military security but not as national security well-being.

There are also earlier studies on this subject. The hypothesis here is slightly different from the studies so far with respect to the status and character of the nation on top.

Most prefer to call the nation on top the superpower. That is because the perception that power rules and human system survives on power. But a more appropriate term in the study of national security is “superstate” while discussing the hierarchy of nations. A nation is a political entity; the state within it has the authority over it. This approach dissociates the term “power” from the concept of national security. But the problem is that the term “power” is widely used in geopolitical circles and hence easy to come to terms with. The term superstate is complicated to perceive as there has been no superstate so far (utmost or maximum well-being) according to this study. It is imaginary but believed to be practical in this study. The prospective candidates for superstates in the future need not be the present-day superpowers at the poles of the binary axes unless they change their tack through national security maximisation. It is not likely. If at all it happens, the world will be on a non-binary singular axis configuration that will replace the binary axes of politics and faith. Is this a fantasy? No sir; no ma’am.

In this virtual hierarchy, in the non-axial format, the top and bottom can be identified and defined positively. While the most powerful country remains at the top, it is the least powerful or the most discounted human system in the form of a nation that remains at the bottom. There is a tendency to call them colonial states. There are many questions here. Can there be only one country at the top? Does that mean polycentric world configuration is improbable? Will the world always be monocentric in its hierarchical order of well-being? Is it possible for power to balance in a hierarchical system of hierarchies? If that is so, will the world ever become monocentric with one superstate on top instead of a superpower with the highest bargaining capability in the global matters? Does it mean the hierarchy of nations has been evolving all these days since the beginning of nation states? That is more than three centuries. Does it mean all that the world had witnessed—the world wars, Cold War, formations of a global commune in the shape of the United Nations, control of nuclear energy, exploration of outer space, etc.—were just the process of a world order with a hierarchy of nations to balance the global community with one on top without a counter force? Will the world hereafter be monocentric or is it for a short while, till someone else catches up and the struggle between the two will lead to cold wars keeping the world bicentric? Does the struggle start at the time when one is crowned as the superstate and the next in line is pacing up to overtake it? Or is it going to be a stage when multinational polycentric form of global attribute is expected? And an interesting epilogue to all the above questions—is the micronisation of erstwhile Soviet Union and Sudan (and similar geo crackers) identical on the larger canvas of human systems?

Shifting the perception to the bottom, one may ask, does the misérables have a choice? This is the unwinding question among the roadblock questions posed so far. Here, one should answer fast. The answer is, “yes.” There is hope for the misérables under the concept of national security. The actualisation of this hope is evident the way the world is progressing. The world is not heading towards despair and disorder. That is the very purpose of creating the hierarchy, even if it is virtual. It is a model in

which the image can be synthesised to understand geostrategy. In its ideal form and mathematically, today's misérables also have the chance of becoming super, at least theoretically, and practically if time is not a barrier and efforts are in that direction under governance aimed at the objectives and focused at the goal.

Governance has the power to turn any nation to a leading nation in the hierarchy of nations. The concept of national security thrives on dynamism and vitality. The opportunities are there for any nation that intends to take the concept seriously. The nation that could qualify for the title role of the superstate today is comparatively a very young nation compared to the majority others in the world—the United States of America, currently a superpower. It was a new nation of people who left their ancestral lands and migrated. It was a new world, a new home away from home for all who settled there. Does this mean that a nation that is young like America has more chances to become a superstate because they are not entangled in the shackles of the distant past? No, America has certain qualifications. Any nation could reach the top or move ahead the hierarchical slabs by raising its NSI. Till then, superstate status is an achievable objective. It is not utopian, not idealised, but realistic. Does history and traditions, however boastful and bragging they may be, block a nation's progress upwards in the virtual hierarchy? Does it mean that the first superstate will be a young country that will be new or an old one that dares to break away from the fetters that bind its feet? It is also important for a superstate to understand the possibility of being toppled over by another on a fine day. It could also be that the world may have more than one superstate on the streets of nations.

Those at the base or virtually in the pit are considered to be colonial states in some studies. This can be refuted by various arguments. One, there are no colonial states, as per the word, today. Second, if the term “colonial state” means that the rulers (the government and its officials, including the armed forces) enjoy greater facility than others, then there are plenty of nations where the people have more than double space between them: the ruling class and the others. Such countries still follow colonial principles or the adage that makes them feel better in government than in non-governmental service. It is therefore better to adjudge the nations as per their wielding power in world affairs according to status. They are the uncared indigenous, cared indigenous, below colonial, colonial, underdeveloped, developing, developed, super developed, and superstate as a thumb rule in a strictly hypothetical manner. The steps in the ladder can be increased as a friend once critically remarked (1994) that he belonged to the fourth world because his country was worse than the third world. “Why should one stop at the third world anyway?” was his argument. This principle, differentiating nations as different worlds, is not followed in the argument here. It is not an acceptable norm in geostrategic security. There is only one world.

The hierarchy of nations as human systems can be visualised as steps (Fig. 16.1). Nations in the hierarchical system are referred to as states. The state provides identity to the people. A step below the states is those human systems where a nation may find a differential in the governing systems. This is especially so with indigenous peoples. In the study of national security, indigenous peoples are equally important human systems. Many of them are not assimilated strictly within a nation state.

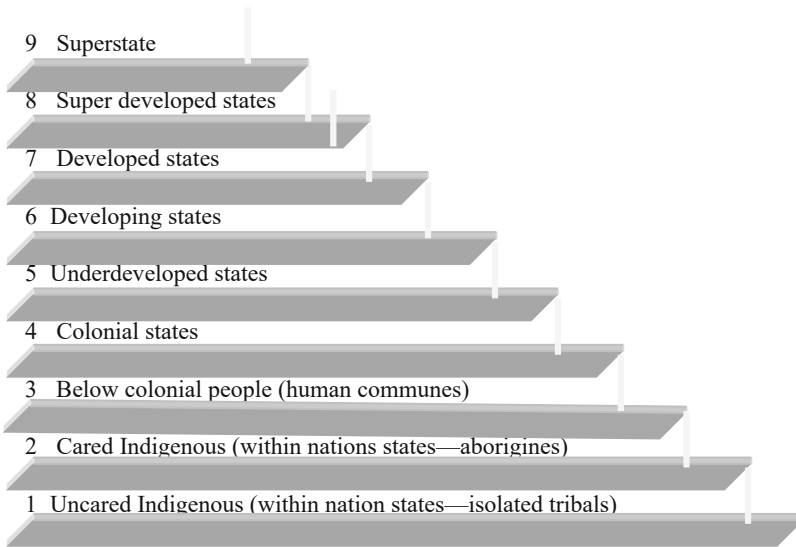

Fig. 16.1 Hypothetical hierarchy of human systems at the geoentity level. (Paleri, P. (2008). *National security: imperatives and challenges*. Tata McGraw-Hill Publishing Company Ltd. p. 264. This system is hypothetical and is used to highlight the concept of superstate which remains at the highest state of well-being and capable of guiding global well-being through specific geoentities. The authority of superstate will be more credible and acceptable to the global systems than that of a superpower.)

There are two oft-quoted terminologies in geostrategic expressions—failed states and failing states. Are they real situations? If so, where do such states stand in the hierarchical structure propounded above? They are interesting questions. A failed state is considered to be the one where there is no effective governance. It brings out a question, “Does a state have control over itself?” The symptoms generally quoted are based on the inabilities of the state to provide services to the public and to collect taxes and a host of other things. It means simply the national security is at rock bottom. The NSI (if and when accepted world over as referred to in this study) could even be negative for such states. It simply means that the state is not governed properly. It also means it could be governed better by another government. The nation either may fall apart or turned around. It could therefore very well fit in the hierarchical structure above—especially in the groove of the underdeveloped or below. It is not a hierarchy by itself. According to a report, there were 60 failed or failing states in the world as on October 2005.²⁴ But the term failing state is a misnomer. The more apt term is failed or failing government.

It is important to understand that in a hierarchical system like this, the citizens of a country do not have to wait for their country to become advanced to enjoy the

²⁴“From Afghanistan to Zimbabwe: The New World Disorder.” *Hindustan Times*, New Delhi. 4 October 2005, p. 12.

benefits of a more advanced one. They could get it just by migration overnight. The superior country of the informal hierarchy may restrict the laws of migration, but certain parameters by demand will prevent it from doing so. Legal affairs in a superior country and the support it provides to the migrant people because of its more civilised or sophisticated governance from the point of view of human rights are the reasons. There will be demand for people for productive activities, because of demographic paucity common to such countries. Whatever may be the shape of hierarchy of nations, it is highly circulatory and turbulent inside. This hypothetical hierarchy inhibits further hierarchies within it at various levels at regional formations and in the form of various cooperative entities. They also settle and migrate further. Human beings get shifted to developed states or superstate from underdeveloped or developing states cutting the middle line. Such migrations can ideally dilute the developed state or the superstate. History has shown that the process of decline of a nation will start many years before its actual collapse. Though, mostly, it is not the time the rot initially sets in that the scholars will research, but the causes to draw parallels with the world of their times. If the decline and fall of the Roman Empire was an ancient treatise on this study,²⁵ then that of the Soviet Union is comparatively recent. In the latter, it started from the time of containment theory of George Kennan in 1947. Gorbachev only shook it when it was about to collapse into 15 different nations including Russia. From the ashes of the great, other nations will rise and build their might. The process continues. Today's Russia is determined to remain in the race in the long run. It is a point of debate whether the Soviet Union would have micronised if it had insisted on remaining shoulder to shoulder with the United States in the race on a win-hold-win path to edge it out at the end. Ideologies may vary, but geostrategy is beyond differences of any kind. It is the approach that matters.

The position at the top need not be permanent. Even though the discussion on the hierarchy of nations is hypothetical, the reality of a monocentric world today and the events that have been and the existence of miserable human settlement in the pit of the civilised world are unquestionable realities. The knowledge here in this argument is not just *a priori* but also heuristic merged in realities of observation. Superstate is a reality and so is the monocentric world. Monocentricity happened only once. That was on the day the Soviet Union fell. If that is so, it is also a reality that it will be replaced one day.

The superpower that has the potential to become the superstate has no history compared to other nations of the world when it started. It started without the shackles of tradition. The absence of history and traditions bound by it was the strength of its people. If the signs were not clear from the beginning, it would have been evident at the end of the First World War. For those who missed it, the projections were clear at the end of the Second World War or when the allied forces landed in Normandy in

²⁵ There have been never-ending variations in the analysis of the decline and fall of the Roman Empire to identify the causes, but serious study will be required to point out the exact date and occasion when the slide commenced in the long winding period that culminated in total decline and fall. It will still remain highly debatable. But in the modern geostrategy, the decline and the growth points can be identified with better accuracy.

the watershed battle of the human race that ended the largest ever war fought in the world. The leadership of the future world was clear and pronounced. The first and prospective superstate of the world was chosen on those beaches on the day of landing. Still, it took half a century for the United States to reach there, well almost. The delay is attributable to flaws in managing geostrategic security. But the fact is that at the moment, there is only one prospective superstate as a sample of the future. There are many hurdles ahead, though.

The United States, under this hypothesis, may be the first superstate the world will witness in actual sense in the future. History has witnessed many powerful nations in its course including their decline. But they were in a much-restricted space. Many of them remained so for a considerably long period. Many had tried to become and remain superpowers but faded out.

A superpower can be a good power broker and an agent of constructive change if sincere and honest. It can broker harmony and tranquillity but cannot guarantee national security within another country. National security of a country is to be seen by itself through effective governance. It has to be done from within, not external to it. National security is an internal affair of a nation that cannot be outsourced. It is the business of individual nations. When dealing with international community including the superpower of the day, it has to turn to geostrategy among other elements of national security. To that extent, the relationship with the superpower(s) has to be established. It is not sensible in geostrategic security to go against the powerful even if one has the potential to outsmart it later. Insularity, obsession and deception do not pay in geostrategic security. The most important vitality ingredient in the case of a superpower is its ability to negotiate for global security. Perhaps its own existence is embedded in its capability to lead global security. But it will not do it. The perception of geostrategic security of the superpower will be based on its retaining power maximisation. That is against its own capability to survive. It is an antithesis of sorts in chaos management. The very argument that proves its existence has to come from its non-existence. That is the tragedy the pharaohs of Egypt faced and the ancient Romans could not evade.

A superpower can induce faith and confidence in affected parties. In most of the cases, the affected party can lose confidence in one's own government. That is when they need someone to broker for peace or to talk on their behalf with force. It is too early for the United Nations to aspire for this force for obvious reasons—majority of its members are weak and its voice is low. An honest superpower can reestablish its own longevity under these conditions. Peace broking and conflict resolution could be credible situations that can be utilised by the superpower to create win-win situations for affected parties.

No nation should underestimate the power of the superpower, even collectively as the United Nations. The power of a superpower can be calculated at every moment, and contrary to the normal thought, it may not be increasing all the time. It will be on a vacillating scale even if it is increasing gradually only to drop by degrees years later. It is obvious and visible. The psychology of superpower and other nations around it along with the United Nations is an intricate and interesting caricature. How long the superpower will remain in that position is important and it will not be

infinite though it will strain to retain the position. It is comparatively in a better position to bargain than others, coercively or otherwise.

How does a superpower retain its personality? Which is the best nation for being a superpower? What ideologies should it follow? United States prepared their way to the status before any other nation even thought about it. Perhaps the turning point was the end of Civil War (1865).²⁶ But it reached that position, strictly speaking, at the end of 1991 when the world became temporarily monocentric with the micronisation of the Soviet Union. Those who argue that the world should be polycentric are correct to the extent of fear that a monocentric world will lead to an autocratic hierarchy of nations. There is no cause to be unduly apprehensive here. Historic biomodels prove that autocratic power projection is short lived and self-destructive. It will be disastrous for a superpower to think of geostrategic autocracy. Instead, it may consider wheel over to superstate by national security maximisation. It is not difficult.

It will be interesting and useful for a nation to check its position relative to superstatedom like a captain does it with the ship on passage through the ocean periodically. The lineup of nations on the track to superstatedom will be interesting to observe. A nation interested in geostrategic security has to behave that way and proceed at the appropriate pace. The course to steer towards destination superstate is different from destination superpower. The latter is very close and more or less relatively fixed and easy to achieve. In comparison, the distance to superstatedom is relatively long, destination moving and highly influenced by human predicaments in appreciating well-being. But the passage will be more challenging, comfortable and conflict free for governance for sapien humans.

Theoretically, the superpower has to decline one day. That is the time when United Nations has to notch upwards to save the turmoil the world will face. Many nations were in turmoil subsequent to the micronisation of a period superpower—the Soviet Union.

People participation is vital to national security. The hierarchy of nation states will also be according to the degree of people participation in governance by national security. It has to be ideally absolute in the case of the superstate. A country riddled with anteforce activism cannot expect to gain healthy people participation. The government may have to change the anteforce to proforce before asking people participation. People generally accept what is good for them and they are aware of it. The problem is in the misconception. It can be changed.

The sustainability of a nation lies in its holding power and ability to withstand the turbulence of governance. It is relatively easy if the track to govern is to superstatedom. The track to superpower is driven by power-hungry governance under the dynamics of the binary polarity. The world may accept a superstate better than a superpower. While the hierarchy of nations could be an acceptable concept to understand the relative positions of nations with respect to each other on the power to a bargain scale, arriving at this disposition may be quite a task for the analysts. An

authentic engagement could be to see how the government treats itself compared to the citizens who are not with them but engaged in other than government occupations. A peep into it and then comparatively examining the world nations may usher a revelation. Table 16.1 is a random example of "relative comfort" of people that clearly indicates the more comfortable is the government employee in a nation, the higher is the poverty outside it.

The table shows disparity, therefore not an ideal format for governance. It is changing, though. This also highlights the adage that the job of a government is not

business, but to facilitate it. The division between the household of a government employee who enjoys an authority-vested comfort under an assured career prospect and those outside it is visible. In all the countries given in the table, the latter is in a relatively uncomfortable position. The gap shows the society is not inclusive. The highest in the table is India where the government employee household has a model income ratio of 5.08. At the lowest end is the United States at 1.02. It is a direct thumb shot that can reveal India's weaknesses in becoming a superstate if ever it could dream, unless it changes. It has a stinking colonial hang-up, if it doesn't know, and the new viceroys are the government servants. Pakistan in second position at 3.87 can have the satisfaction of being better than India, though it remains colonial and equally disoriented. Obviously, neocolonialism prevails among such countries. There are quite a few along with India—China, Pakistan, the Philippines, Russia, etc.—whose governments miss out on authentic engagement with people in nation building. The question from a rear-view mirror approach is how such nations could ever dream of becoming superstates one day unless they bring the ratio to 1:1 or close to it. Such nations may become economically strong but will not have the benefits shared equally for an authentic engagement of its citizens towards human well-being. This ratio may also matter in calculating the NSI, which needs to be researched seriously.

16.5.1 Hierarchy and Polarity of Nations

One of the findings of this study is the previously discussed binary bipolar balancing of the human systems of the world based on the flow of power through (1) politics and (2) the faith of the people under belief systems. The compounded effect makes them seek out beyond the reality of limitations in expectations of not only perceived security but also apparent security.

Within this state of centrifugal balance similar to that of a spinning top, the world will always have a country as a geopolitical entity at the top which ideally should be the superstate. But it is not the scenario at present as no nation qualifies for a superstate since the system lacks the metrics and tools of governance under the concept that is highlighted here—national security. The one who has more military and economic power than others (rather, the power to control and bind others) will be termed superpower which doesn't carry much sense in human well-being since how super a superpower should be is not defined or calibrated for validation and exactness. Superpower is a relative term within a group. It will depend upon the average power of the group. A superstate in the opposite is different. It will have the NSI above the considered level. The word is not governed today according to the concept of national security advocated here. It is governed based on power maximisation either politically or based on belief system polarities. They are fused, though. This study is for the future when the governments find it primal to drive along the familiar. The idea of superstate is applicable only under the concept of national security explained here. Hence, it lacks validity at the moment. Ideally, the

metric should be the NSI for which there are no identified yardsticks so far. They are expected to come. In that case, either a single state or a group of states above certain level of NSI could be considered for the superstate conglomeration at the two poles that may gradually merge or turn to a matrix. Or perhaps the world will turn around to a unipolar system with or without conflicts under the global security concept. One doesn't know unless seriously researched. There is no hurry. Even otherwise hurry is insignificant and incidental under the limitations of natural frequency of human system evolution. There are only two choices: wait patiently or improve as sapien human intellectually without waiting for genetic modification. The latter is possible, this study believes, by governance and individually focused development.

As seen in the earlier statement, there are two nations at the two poles of the power axis. The nations are symbols of relative political power, though chosen faiths may be driving them. On the second axis, there are two faiths powering it like the poles of a battery. These are based on belief systems. It could be one of the three—cultural religion, religious culture or politico-religious culture. There are no belief systems stronger than them at the moment. The elements of politico-religious culture will also be found smeared on the political axis. In fact, this aspect masks the axes or makes the second axes invisible in the first one. In fact, each axis complements the other. This is what is not clear at the moment as careful evaluation of the influence of religion on national governance in tandem with political governance is required in an unprejudiced scenario. The bias is difficult to expunge; hence, the ensemble of global and national polarities will be difficult to appreciate expressively. The political culture as a religion is a new development since the advent of communism which is now split into splinters, each surgical sharp. All these make things crowded, but not complicated. Besides, all these from a strategist's view point are natural in human systems considering the gumbo brewed out of human singularity and differentiability. The two axes around which humans conglomerate in the dynamic centrifuge will have both the power of politics and faith smeared on them. In this scenario, the centre point is where the binary axes cross. It is the critical point for a nation to observe for its geostrategy. It is the quadripoint²⁷ that divides the world in a geostrategic boundary (Fig. 16.2). Depending upon the position, the nations will find their geostrategic scenario changing. A nation can be closer to a particular axis or away from the axis or closer to the quadripoint or away from it (Box 16.2). Their geostrategy will accordingly change. It is important to understand here that the axes are not terrain boundaries but the boundaries created by the global powers and faith balance. The power and faith of the nations will not match at any time but will remain dynamic and advance or retreat from the previous positions slowly in almost all the cases. In fact, the incremental changes in position will not be noticeable or realisable. The mp of power balance will become a plot for governments to keep for crafting geostrategy.

The diagram in Fig. 16.1 is subject to the following assumptions:

²⁷ Known as the four corners in North America.

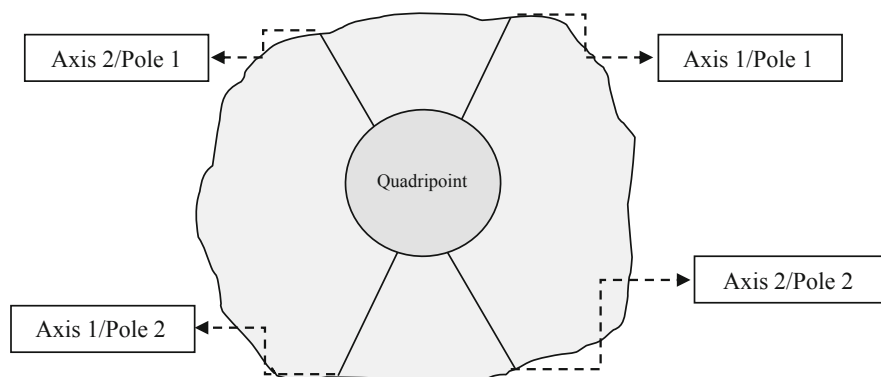

Fig. 16.2 Hypothetical diagram for a geostrategic plot of quadripoint

- The global human system is behavioural of the people who occupy it.
- The system is dynamically moving forward as if churning in a centrifuge which has binary axes, each having its own bipolar fluxes that keeps them balancing.
- One is based on political power as a nation and the other on the power of prevailing belief systems as faith.
- The two binary axes and the four poles (two each) can be identified but are not done in this study as it is not relevant and the situations can change.
- The axes are almost fused, though the gaps are telling and also widen at different times. The gap causes the wobble in geostrategic affairs.
- The system dynamics can be compared with a centrifuge of forces caused by governance and various other factors.
- This makes the geoentities move around the centrifuge and their position changes with respect to the quadripoint that is common to all and the most stable.
- This plot can be used if marked carefully, correctly and continuously to appreciate the positions of the nations to handle them geostrategically as if on a tactical plot.
- This plot can also give information about the trendlines in the geostrategic changes that are likely to happen in the future and perhaps more.

Box 16.2: What Is the Quadripoint in Geostrategic Security Assessment?

Quadripoint is also a junction—quadrjunction, similar to trijunction when three nations share a common border. This term is taken from border security for application in geostrategy and mainly for plotting the position of nations geostrategically relative to the quadripoint of the binary axes of politics and belief systems. The drawing is hypothetical, though it can very well be used in geostrategic appreciation by experts. This study will be more useful for citizens to appreciate where their government has taken their nation

(continued)

Box 16.2 (continued)

geostrategically—close or away from the stable quadripoint. Closer will be better than farther since the nation will have more opportunities to gain the axial balance and thereby a superstate one day. The role of government is to keep the nation close to the quadripoint of the binary axis system. Being geostrategic and not spatial, it is quite possible for more than one nation to be in the same point. The dimension of the diagram is no physical but strategic.

16.6 International Systems

Geostrategic security has to function within the international system that will be contemporary to the ongoing and evolving global system. The difficulty is that there will not be a *consensus ad idem* among those who matter in geostrategy about the prevailing global system. Opinions will differ and that will make the already complex system more difficult to appreciate. Correct appreciation of the system is necessary to understand its process of evolution that impacts upon geostrategic decisions. The highest body in a country that deals with geostrategy or, to that extent, the individual who heads it should be thorough with the perception within all the differing views. It has to be the person who is charged with the responsibility of taking care of the people of the country and their well-being—the president, prime minister, constitutional monarch or anybody on whom rests the ultimate accountability. Tough it sounds, but not so in reality. The historic international system is the basis and provides enough clues on how contemporary systems will work. People have not changed, people make nations, and it is the same people who interact today, though their appearance may have changed including the mode of transport and the language they speak. That is not a major change in national security parlance. The actors may have changed, but acting continues in its inimitable manner in the global arcade since the days of Kautilya. Today, geostrategy is also about sincerity and winning. There is no place for wily approaches and deception. Unlike in the earlier days of history, diplomacy sans deception is the acceptable choice for the future.

There are many comparisons of historical systems with contemporary international systems. Changes in the systems originated with changes in the administrative systems, challenges faced by more powerful from the less powerful, ideologies, changes in the distribution of power, political fragmentations, etc., heralded changes in the international systems. In the modern system, the doctrine of sovereignty plays an important part. There are many parallels and cyclical patterns. A successful invasion by outsiders was the result of fragmentation from within when the states imploded and became more insecure. History can repeat in the contemporary global system and a close look will reveal examples of such repetitions. According to Holsti, when analysing the contemporary system, the main question is, “What is new

and what is mainly a continuation of the past international practices?”²⁸ It is an excellent approach path.

Changes in geostrategy can be every moment; it is that fast. It is clear when one compares the plans a country had yesterday with those it has today. Geostrategy turns around reality of the day, not the perception of yesterday. The ability in understanding the reality of the day if sharpened by clear perception of the reality of the future will make the difference. The secret of geostrategic security lies in this capability—to understand the future. In international relations, it is partially hidden in the past.

The Westphalian rules of nation states assumed the use of force as state policy. The force was to be exercised through the armed forces by traditions of just war. There are opinions today that an armed force is not exactly one of the instruments of statecraft, as perceived till the late nineteenth century. At present, force is said to be used only for self-defence individually or collectively or as coercive sanctions approved by international organisations. It may change as seen from the use of force by the superpower and its allies in the Iraq War of 2003. This was termed the pre-emptive use of force. It did not have the approval of the Security Council according to Kofi Annan, the secretary general of the United Nations. Kofi Annan’s statement was countered by the president of the United States in his address in the Security Council as incorrect. It shows that the superpower, though more powerful than the United Nations (the very act in Iraq proves it), was subconsciously willing to abide by the UN Charter. The CIA was accused of attempting to falsify reports on Iraq’s alleged but not proved weapons of mass destruction programme.²⁹ The contradictions show that the UN Charter is a deficient instrument with respect to the problems of the day. It is half a century old and perhaps not suitable to the changing world. That is putting it diplomatically. War still remains a force of negotiation. Therefore, the armed forces, the instruments of policy of the relatively powerful, continue their force projection role in statecraft. Things have not changed much since the Westphalian days. Even the power of supranational authorities is serious to reckon with, whether it is religion or sheer national power. Obviously, it is naive to expect human systems change at a speed that is beyond the natural frequency of generations so far.

Over the years, scholars have defined different independent models of international politics. Holsti identified five models that may serve the purpose of choice in geostrategic thinking in national security.³⁰ They serve as the basement cellar for a peek at the ground level standing below it before a decision is taken. These models are eye-level indicators of geostrategy. National security and its element of geostrategy can use them as protective models to cover while taking a decision. They are empirical models termed as “*realism*,” the “*society of states*,” “*pluralist*—

²⁸Holsti, K.J. (1992). *International politics—a framework for analysis*. Prentice Hall. p. 44.

²⁹“CIA Agent was Told to Falsify WMD Reports.” *The Times of India* (Mumbai), 10 December 2004, p. 13.

³⁰Holsti, K.J. (1992). *International politics—a framework for analysis*. Prentice Hall. p. 67.

interdependence,” “*dependency*,” and “*world society*.” Each model is different and the views of scholars under each of these models are also different. There may be other models too that one could identify.

Thucydides,³¹ Machiavelli (1469–1527)³² and others in the very early days and more recently Hans J. Morgenthau (1904–1980)³³ advocated the first model: the *realism model*. In realism, the authority is with the state and only the state to manage its affairs in international relationships. There is no superordinate authority to decide the relations between sovereigns.³⁴

Society of states mentions about bonds and institutions between a group of states. It naturally exists as today’s events show. The underlying reason is security that the state may feel threatened by external forces. In spite of formation of nation states since 1648, there is substantial insecurity in the world. Many wars were fought between nations. There are countless crises. Hence, to protect the sovereignty and independence of states, societies of states are modeled. Slowly with internal rules of the game and rules of diplomatic engagements, the society of states gets formalised in which all states stand to gain.

The so-called non-state actors³⁵ and other extraneous entities have a place in *pluralistic–interdependence model* which is more based on politico-economic problems of a state. In the modern global system, there are many policy sectors that bear on each other in decision-making. In such models, there is certain amount of vulnerability the states experience because of interdependability of the state with non-state actors. National economies are interconnected. As a result, many new issues arise. The problems keep the issues of war and conflict at bay. It is trade, economics and industry that surface in discussions. National power is not military power and the armed forces are naturally and rightfully pushed behind. The more the nations become interdependent, the less likely are wars among each other.

The *dependency model* springs out from interdependence. There are asymmetries and inequalities in the relationships among nations. These characteristics come up as salient points in the international relationships of nations. The dynamics of internationalism is driven by capitalism since the colonial days that still continues as

³¹ Encyclopaedia Britannica. Ultimate Reference Suite. CD-ROM. 2004. Thucydides was ancient Greek Historian. He wrote about the Peloponnesian War. His work was the first recorded political and moral analysis of a nation’s war policies.

³² Ibid. Italian writer and statesman. Original political theorist whose work “*The Prince*” is a treatise on the subject. His book brought him a reputation of amoral cynicism.

³³ Hans Joachim Morgenthau, a German born American political scientist, was a leading analyst on the role of power in international politics.

³⁴ Holsti, K.J. (1992). *International politics—a framework for analysis*. Prentice Hall. p. 67.

³⁵ The author stands by his argument that nonstate actors do not exist as the term could be quite misleading though used frequently. According to the argument every human is classified by his or her existential identity as a citizen of a country. Some may have multistate citizenship, but there could be none without a state. Therefore the so called nonstate actor is widely supported by at least one state or more. The state is the actor and the citizen in a so called nonstate activity is only the protagonist.

neo-colonialism. It is market driven and the more powerful wants access to resources. There is a tie between economics and politics in the dependency model also. The overall economic picture is one of pronounced dependency, not interdependence. In this model, there is coercion by industrial countries over developing countries. Whether it is for education or job, the flow is from less developed to more developed which in certain aspects look natural but is a sign of dependency according to this model.

The *world society model* shares some feature of the last two models: pluralist–interdependency and dependency models. This model suggests that the world has to be seen globally and the socio-econo-security matters are embedded within the global perspective. According to Holsti, the main characteristic of the global system is its social unity.³⁶ The world, according to this model, is heading towards a global system in international relations. It believes in the principle that the global system is superior to nations and only it has the capability to resolve issues of the world since nations, religions and institutions are comparatively helpless.

These models depict contemporary global systems in international relations according to Holsti. Every model is based on certain assessments. The question is, whether these models stop here or is there a scope for additional models in the international system? Will these models dissolve into each other in the course of time? It is a question to ponder.

A close look will reveal that the world, whether historical or contemporary, has nothing much to offer as change towards the betterment of society and will move in its own pace unless nation states put up efforts in that direction. It is important for the nations to have their sovereignty and independence unquestionably retained in a healthy state and the well-being of its people maximised. In this process, whatever model a nation state assumes could be acceptable as long as it is in no way conflicting with the national security maximisation efforts of another nation. In such cases, there will be geostrategic deficit. The greatest institution that could stand alone as a rejuvenator between the historical and contemporary international system is the United Nations. The concept of the United Nations has changed the models and their approach aspects. The world models for contemporary system, therefore, will be defined involving the United Nations as an ingredient in the international system and the process it adopts and its future existence in the world. It has to be also seen from the concept of superpower that has been explained earlier. If these two arguments and their interplay are acceptable, then there is another model in the offing—the sixth one, according to this study.

The sixth model is the “*global protective model*.” In this model, the nations are not bound by themselves for decisions. The governments may face (acceptable) setbacks within their systems of governance but have the backing of the world of nations in their continuity towards national security maximisation, though there are many acts beyond the capability of a nation and their primary supporters like upgraded acts of terror that may demolish this hypothesis. The probability of

³⁶Ibid., p. 77.

many such events in the future is comparatively high. In that case, one may have to limp back to the five-model theory of internationalism. Here, the five models were examined only to drive home the sixth principle in modeling an international system. It is the sixth model that has the potential to germinate the idea of global security explained later in this book. There are many purposes envisaged while defining the foreign policy of a nation. In this book, the interest is only related to national security within the community of nations. Geostrategic security is one of the identified elements, and therefore, its optimisation is mandatory for NS_{max} .

16.7 Ideologies and International Relationships

It has been said that ideology has transformed international relationships in the twentieth century—in appearance at least. Earlier centuries experienced dynastic, nationalistic, civil and imperial wars. Diplomacy was designed to further national interests through international interactions: security, expansion, trade and tranquil relationships in the name of peace. Such factors, indeed, appeared to govern international relations until recent times. International relations today are seemingly dominated more often than not by the exigencies of “-isms” and “-ologies”: wars are fought, alliances are made, and treaties are signed based on ideological considerations. The balance of power in the contemporary world is a balance weighted by ideological commitment. “The Communist bloc” confronts “the free peoples,” and in the “Third World,” emergent nations cultivate a nationalist, anti-colonialist ideology in their search for identity and their efforts to achieve modernity. But this is not to assert that ideological wars or ideological diplomacy are entirely new. Ideology has been the most conspicuous element in international relations. It is necessary here to distinguish between the actual events of history and the interpretations that are put on history, for some events that lend themselves more readily than others to an ideological interpretation. The ideological perspective has become increasingly significant, as the general public has come to play a role in considering questions of war and peace. When questions of defence and diplomacy were settled by kings and their ministers and wars were fought by professional soldiers, the public was not expected to have any opinion about international relations, and in such a situation, there was little place for ideology.

16.8 Geostrategy and Natives: Hyphenated or Otherwise

It is interesting to find citizens whose nationality is qualified with a hyphen in the middle. There are many. The hyphen stands prominently in the middle when expressed as a citizen. It has a take on ethnic security concerns in a security (Chap. 20), which is another matter. The global process of human migration and settlement has familiar procedures. People travel and settle down in a new country.

Some of them treat the new place as their country. They face resistance from those who are already there. Thereafter, they resist others who come later like them. Ultimately, all of them settle down in the new country of their own. There is a difference, though. They become hyphenated: Indian-American, Sri Lankan-Indian, Tamil-Sri Lankan, African-American, Chinese-Singaporean, Latin-American, etc. Among the migrants, one set ultimately takes the lead and decides they are the originals. Humans are funny even without a visible tail. Members of the hyphenated community often draw on the hyphen to step aside from the originals in character and personality. There lay the mindsets caught in the omniweb of human duality.

Duality, even if the new citizen does not get dual citizenships, is a dumpling in the soul from the point of view of nationality and nationalism. The duality is becoming stronger in today's concept where the early settlers consider themselves as the "natives" after replacing the original natives by elimination or hyphenation. In fact, there is also a certain degree of credibility deficit here with respect to nativism and indigenous life. Strictly, the natives are the indigenous people. The rests are all hyphenated, irrespective of when they migrated. The neonatives, under hyphenation, retain somewhere in the corner of their minds a passing thought about their native country often with anger laced with retaliatory depression. The retaliatory depression is active with a tendency to react about their country of origin. The reaction comes out with anger, praise or regressive tendencies. Powerful nostalgia will be in the forefront. The cultural conditioning will be visible. It is a social behaviour aspect of a neonative—the recent settler. There is a deep-rooted geostrategic opportunity here. Many countries have recognised this opportunity, and for some, it has become a responsibility—a kind of obligation to see that the country tickles the root behaviour of their original people who are non-foreign citizens. India, China and other Asian countries feel that way. It has also now become a strategic appreciation for Arab countries.

India held a meeting to welcome and woo Indians from outside in 2003 for the first time in its history. It was dubbed as the *Pravasi Bharathiya Divas* (the day of the foreign Indians). The aim, as proclaimed, was to expatriate the "patriotism"³⁷ and potential of the great Indian diaspora. India even offered dual citizenship to a select few.³⁸ This was already experimented by China. Seventy percent (2003) of the FDI amounting to US\$40 billion is contributed by the Chinese abroad.³⁹ That was a catalyst to the economic growth of China in the recent years. Obviously, for India, the inspiration was China. In this action, the government visualises them as a source of fiscal capital. But the potentials are not only in the element of economic security but also in other elements of national security. The Chinese have created a strong network of about 20 million Chinese origin people settled abroad. The Chinatowns

³⁷ The term patriotism is a misfit here and is also in strategic appreciation, because of the abstractionism involved in it.

³⁸ Pal, H. "India Takes Chinese Steps to get a Move on NRI\$." *The Economic Times*, New Delhi, 9 January 2003, p. 1.

³⁹ Ibid.

are special communes with mini “great walls.” China invested heavily in its hyphenated people abroad.⁴⁰ China engaged its original people settled abroad through high power networks since 1995. It is a lesson in geostrategy.

India followed suit when it decided to celebrate the *Pravasi Day* on January 9 every year. That was the day when Gandhi returned to India from South Africa in 1915. The Indian diaspora abroad is quite substantial.⁴¹

India was the leading country of origin of international migrants in 2019 with a 17.5 million strong diaspora, according to new estimates released by the United Nations, which said the number of migrants globally reached an estimated 272 million.⁴² It also meant their parent nations and the host nations would have to rely heavily on geostrategic security for their well-being. The dataset on international migrants is usually released by the UN Department of Economic and Social Affairs (DESA) annually. It provides the latest estimates of international migrants by age, gender and origin for all countries. Interestingly, what should matter more in national security studies is why the migrants are there. The reason is not difficult to identify unless one is looking for individual reason. In a collective psychological term, it can be said that a migrant is prone to dynamic locomotion.⁴³ But the reason that the migrant will give will be based on a situation veiled in uncertainty. It will not be a deep-rooted reason accountable to personality traits of locomotion. If it is population that pulls the trigger or pushes the people out, then India should be followed by China. Whereas it can be seen that Mexico leads China in international migrant population (Table 16.2).⁴⁴

What makes people move across the planet still holding on to the land clasp syndrome of Boris’ (Chap. 11) father will be an interesting study. This is a key factor (why people move) in geostrategy. The primary reason in this study is the personality trait based on locomotion—primarily dynamism. People who are dynamically into locomotion are comfortable in traveling around. They do not need a reason but reasons help them to step out. The statics move within a limited radius which could also be cross border. The arrested seldom move. It will be interesting to identify the present generation of the people Darwin carried with him for experiments from

Galapagos, the iguana land. In the tortoise reserve on Santa Cruz Island in Galapagos, there was a sign at one point that says bluntly, “Stop. Do not go beyond this point. You could die.” But a “dynamic” person may still go beyond it and die, immutable.

A nation’s diaspora is a good global influencer. It depends upon their per capita income and sheer presence.⁴⁵ It is economic and political at the same time. Outflux of diaspora is influx of international respect and credibility. The areas are many: healthcare, food, science and technology, service industries, ideas, knowledge banking, etc. These people, irrespective of their countries of origin or parental origin, have contributed substantially for the socio-economic well-being of the countries of their citizenship and continue doing so. It is a step towards global security concept (and a supporter of the *global protective model* explained earlier), though the world may not realise it at the moment. The migrants may differ from each other, but they have one thing in common—a complex migratory psyche. The psyche is in search of opportunity coupled with restlessness induced by impatience. Irrespective of what it may be, emigrant communities imbibe each other’s values and emanate confidence of pluralism in almost secular environment. These are the signs of the world’s movement towards global security concept. Hence, supporting and being concerned about the people of a nation settled elsewhere are like promoting the harbingers of the future that is prosperous and much advanced in civility. They ring in goodness for humanity. That is the reason why the offshore personnel of a nation that settled elsewhere is one of the main components of geostrategic security for a nation. A migrant works harder for this reason. The migrants can be reconnected with their countries of origin easily. They can be part of the process of national security maximisation in both countries—their country of origin and their country of citizenship, provided they are geostrategically anchored well in the system. This is the responsibility of both the governments within the element of geostrategic security.

The hyphenated community abroad (Box 16.3) is a strong bridge in geostrategy that is mutually beneficial. Prudent governments will recognise the facts. An

⁴⁵ Khosla, V. “Education and Ideas: The Punch that the Diaspora can Deliver.” *The Economic Times*, New Delhi, 9 January 2003, p. 1.

example was the debacle that caused to Uganda when Idi Amin (1925–2003)⁴⁶ expelled the people of foreign origin from the country, especially the Israelis and the Indians, though most of them were hyphenated British citizens. The country and Idi Amin's regime paid heavily for that action that ended in the hostage rescue action at Entebbe on 3–4 July 1976. Hitler lost touch with reality and thereby geostrategy when he ordered ousting of the Jews. These are serious geostrategic errors in history that caused a government to lose its nation or the nation its government.

Box 16.3: Hyphenation: Does It Lack Ethnic Decency?

Though used widely to explicate a migrant citizen selectively, this study considers hyphenation of citizens invokes ethnic insecurity and is not an appropriate bioethical usage in the modern world of sapien humans. Simply to say, it exhorts disrespect to human dignity. Hyphenation to stamp a person about his or her origin is practised in the United States of America and followed by others, though not with conscious intention of malice. Humans like any other life form belong to planet Earth but pushed by themselves or their own to exclusive niches of settlements called the nations as if fashionably incarcerated. It is fine and all is well. But it is time that at least in a nation, its citizens are known without any tails of ethnicity—as a citizen of the planet with a nationality. Even alphanumericism like R2D2⁴⁷ will be fine instead of a name to address or remember. Already there are many such ethnic tails that cause disharmony and it may be better if the nations and the human system globally refrain from hyphenation. Instead, people may be allotted double citizenship status on double permits such as passports or other identities. Geostrategy and diplomacy are long overdue for a hot wash and overhaul in toto.

16.9 United Nations: Controlled Collectivism in an Uncertain World

The United Nations came under a low after the invasion of Iraq by the US lead forces in 2003. It was not for the first time its credibility was tested. The focal point of its credibility lies in its international character formed out of the consternation in the aftermath of the Second World War, not strictly in its charter. The world did not want another war of that magnitude. It also means, rather can be taken as, smaller wars are

⁴⁶ Military president of Uganda from 1971 to 1989.

⁴⁷ R2D2 was a non-human character in the Hollywood serial movie, Star Wars, though with a man standing inside the external armour sort of costume to manipulate it in movie action. In the script, R2D2 was considered to be a heroic astromech droid that did well for its masters. The audience appreciated it. The immensely successful movies in the Star Wars series, with the first in 1977, were created by George Lucas. R2D2 was controlled first by Kenny George Baker and later by Jimmy Wee.

fine. Though established on 24 October 1945, the concept was already there with the League of Nations (LON) for more or less similar reasons at the end of the First World War. The purpose in both the cases was to protect the succeeding generations from the scourge of war. The League of Nations met for the first time on 15 November 1920. Forty-two nations represented. The president of the United States Woodrow Wilson (1856–1924) strongly favoured the idea as a means of preventing another destructive world war. The league covenant was based on the principles of collective security by joint action of the member states against an aggressor and other matters. The covenant was part of the Treaty of Versailles on 28 January 1919 that brought the end of the First World War.

During the 1920s, the League assimilated new members and experienced no serious challenges to its authority. Soon it was weakened by the situations on ground. The non-adherence of the United States when the US Congress failed to ratify the Treaty of Versailles that contained the covenant was a serious setback in irony. The United States never became a member. One of the League's main purposes in preventing aggression was to preserve the status quo as established by the post-First World War peace treaties. In the 1930s, when dissatisfied nations undertook to upset this arrangement and other major powers declined to enforce it, the League, which had no power other than that of its member states, was unable to take action. Discredited by its failure to prevent Japanese expansion in Manchuria and China, Italy's conquest of Ethiopia and Hitler's repudiation of the Versailles treaty, the League ceased its activities during the Second World War. The last meeting was held on 8 April 1946 by which time it was superseded by the United Nations, which inherited many of its purposes and methods and much of its structure.

The lesson for the United Nations and the assurance for the world community for its continued existence in honouring its charter and meeting the demands of the world to avoid serious destruction by war lie in the 26 years life span of the League of Nations as a biomodel. The United Nations survived many tests in the twentieth century. It faced a more serious test in the beginning of the twenty-first century—the world's first netcentric war unleashed on Iraq by the United States and its allies in 2003. It was said to be a pre-emptive attack controlled from a new terrain—the outer space. Does the charter permit such pre-emptive strikes? Not yet. It amounts a violation parallel to the counter events of League of Nations enough to drop the credibility of the United Nations to an all-time low since its inception. But how many wars so far fought in the world have the approval of the United Nations supported by its charter? Though the credibility deficit of the UN peaked with the invasion of Iraq, there are no signs of its existence being questioned. The then secretary general Kofi Annan and the members of the United Nations were able to survive the resonance in charter was another matter. It shows the resilience the United Nations has acquired in its attitude in the half century of existence. It would have collapsed like the League of Nations if it were in the late 1940s when geostrategic security concept was in its

early stages.⁴⁸ The Iraq invasion had all the ingredients of ally formation on either side with the symptoms of a catalyst for the twenty-first century world war. The advanced world was able to appreciate the situation better. It showed geostrategic maturity acquired in the course of time and its applicability at crucial times in international affairs for the common good of humankind. The United Nations too has to survive.

Kofi Annan's success here is in diversion. He appointed a commission. The result is not the promise for modern reforms that will change the international organisation into an unshakeable giant. It is virtually impossible for a long time to come. Perhaps, the secretary general was aware of it. He was clever to divert the attention of the world from criticisms by making it believe that the United Nations was in control, and it is very much needed for the future. He knew his bold statements were not sufficient in the geostrategic cacophony of the world controlled by powerful nations. A commission could do well in situation like that. Kofi Annan's decisions reflected the acuity and expertise of a corporate chief. It was a great tactical victory for the United Nations by distraction and hope. Such leadership and clever games were not available at the deathbed of the League of Nations. Probably, it was too early. Though Kofi Annan has done the best he could think of, reengineering the United Nations could be still an impossible dream. Amending the charter and agreeing on the reforms are not going to be easy. The Achilles' heel of the United Nations lies in the power of the so-called big five to veto. The death knell of the United Nations is hidden in it. A peep into the arms' sales of the five veto-empowered nations and the power they wield is sufficient to prove this premise. It is the veto power that will decline them one day and set the motion for the fall of the United Nations. Is there a choice? There are plenty. One is to abolish the veto power in toto and opt for two-third (or any convenient) majorities with additional members in the Security Council. The age of the veto is over with the Cold War. The world will not relent now to abolish veto power. If delayed, perhaps the turning point, towards the transmogrification, if not the beginning of the end, of the United Nations will originate from here. The comparatively and forwardly refined world understands the need for an international organisation like the United Nations. It is evident in its membership that stood at 191 in 2004 compared to the 51 in the beginning.⁴⁹ But it cannot end up as an epitome of a colonial hierarchy in the civilised world. Consensus is the word for civility—not veto.

Kofi Annan's panel was tasked to examine the new global threats (Is the global security concept evolving? If so, how far it has come?), analyse challenges and opportunities and recommend changes to ensure collective action to deal with them. One of the areas was the composition of the Security Council. That, perhaps, will be the weakest part where their reforms may find many glitches that may essentially come from the Achilles' heel of the United Nations—the unquestioning veto system,

⁴⁸It is important to understand here that the United Nations was not a replacement for LON.

⁴⁹The initial 51 was the 50 founder members and Poland. There are 3 members in 2021. The 193rd member was South Sudan (14 July 2011).

mentioned earlier. The panel recommendations sum up the need for changing the 1945 power balance by expanding the Security Council and bringing out the question of pre-emptive military strikes.

In the beginning, the Security Council had 11 members, five permanent and six elected for two-year non-renewable terms. Later, in the late 1960s, the membership was expanded to 10 in the non-permanent category. The permanent members were the United States, the United Kingdom, China, France and Russia—the geostrategic top five of the world, at the time the United Nations was formed. Among them, the United States graduated to the level of the first superpower and the superstate in the hierarchy of nations in 1991. Its clout beyond the veto was clear and visible since then. Today, it has a status that demand productive cooperation and interdependence with the United Nations—it is in but like to play from outside. It also brings out another theory that the superstate will play from outside the United Nations—the rest of the world—and though may not be a referee or a cop. Whoever dares to take on will be dared to. There is no choice, mathematically. The interdependency factor is not an exaggeration, but a reality since the superpowerdom cannot be permanent. It will need the United Nations just like the way the United Nations needs the superpower. There is a mutuality application and though may not be exactly like that of the sea anemone and the hermit crab in mutual existence.

The hierarchy of the Security Council and, to that extent, the entire United Nations is not only orthodox but also based on geostrategic power balance. The chance for the next superpower, which is a certainty however long it may take, is high for those in this veto corridor. The proposal for any other nation to get into it will be extremely remote unless it has the power to push rather than get itself pulled in, though it matters a great extent. It has to come from geostrategic security. But the turn of events may be different since veto power reduces collective strength. The more a prospective incumbent seeks veto power, the more it will be resisted by the inherent conditions of power within the Security Council.

There were attempts and working groups in the past to change the system. Nothing worked. The complacency got a jolt with the Iraq invasion that questioned the relevancy of the United Nations. Kofi Annan's team would have gone through an existential introspection. A new panel was formed. It is reported that the panel too had problems in consensus. It was natural. The panel submitted its report on 30 November 2004. The recommendations included overhaul of the Security Council and holding out legitimacy that it could grant pre-emptive strikes by the military. The changes are for increasing the Security Council membership from 15 to 24 members. The panel put two proposals since they could not agree. One alternative was to add six new permanent members⁵⁰ and three additional non-permanent members. That would make it 11 permanent and 13 non-permanent members for 2 years. Other option was for a new tier of eight semi-permanent members chosen for a renewable 4-year term. And one additional 2-year term each to the existing 10—that means five

⁵⁰The likely candidates are Brazil, Egypt, Germany, India and Japan and either Nigeria or South Africa.

Table 16.3 Security Council lineup and proposals^a

Table 16.4 Security council lineup and status 2021^a

		Members
Permanent	5	China, France, the Russian Federation, the United Kingdom and the United States
Two-year term	10	Estonia, Niger, Saint Vincent and Grenadines and Vietnam (ending 2021) India, Ireland, Kenya, Mexico and Norway (ending 2022)

^aA State that is not a member of the Security Council may participate, without a vote, in its discussions when the Council considers that country's interests are affected. Both Members and non-members of the United Nations, if they are parties to a dispute being considered by the Council, may be invited to take part, without a vote, in the Council's discussions; the Council sets the conditions for participation by a non-member State

permanent members with eight non-permanent members on a 4-year term and 11 non-permanent members on a 2-year term. Veto will be limited to the original five. An interesting point here was the number 24, a figure with which the United States was said to be comfortable.⁵¹ It showed the external influence a superstate could wield in an international organisation. Eroding the powers of veto would be another issue of contention. Russia had stated it was against it⁵² and so the others would view. Table 16.3 sums up the position and proposal for revamping the Security Council. Table 16.4 shows the lineup and status in 2021.

The panel projected 101 recommendations. Changes would require amendments to the UN Charter.⁵³ Approval of the General Assembly would be required by the two-third majority in the 191 member states (then) including all five permanent members followed by ratification by legislators of their governments. Among the panel's recommendations, the criteria for membership in the Security Council would be the financial, military and diplomatic contributions the states made to the United Nations. The criterion for developed countries would be the progress in meeting the

⁵¹ Garekhan, C.R. "Join the Club." *Hindustan Times*, New Delhi. 7 December 2004. p. 10.

⁵² Saurabh Shukla. "UN Seat Yes, Veto No." *Hindustan Times*, New Delhi. 4 December 2004. p. 1.

⁵³ Among these recommendations, serials 97–101 of the panel deal with changes in the UN Charter: any amendment to Article 23 required by proposed reforms; Articles 53 to 107 are considered outdated; deletion of Chapter XIII on the Trusteeship Council; Article 47 on the Military Staff Committee and all references to the Committee in Articles 26, 45 and 46; and a call to all member states for rededication to the purposes and principles of the Charter, respectively.

internationally agreed target of 0.7 percent of their GDP for official development assistance (ODA).⁵⁴

There will be hectic lobbying for a chosen model. This will intrude into the geostrategic parities (strategic, economic, political, social, human rights and diplomatic parities) among nations that competed for a seat in the Security Council. The hierarchy gets confirmed. The evolution of the Security Council will also show the evolution of a new geostrategic power structure in the world. The acceptability of the new power structure to those already in the compartment has to be seen. The *Washington Post* criticised the panel's recommendation stating they were flawed. According to them, the United Nation's role was to project Washington's policy and American power to the world.⁵⁵ The simple statement substantiates the role the United States has assigned to itself with respect to the United Nations—there is something wrong here that the superstate has to understand for its own sake, not that of the heaven's.

Kofi Annan, the secretary general, amazingly succeeded in bringing a revived interest in the United Nations by convening the commission to bring about changes in the United Nations to meet the new challenges to global security. It served as a diversionary approach when the UN scrips crashed to an all-time low post Iraqi invasion. The Secretary General had to show that the United Nations still holds and will not wean away from the world the League of Nations way. If that was so, the United Nations will go on, if not on results, on hope for the future with the 101 recommendations of the panel. But it may be a warning to the members associated with the problems. The United Nations faces a host of problems, some of them quite sleazy—finances; US supremacy and intimidation (lack of advancement opportunities for employees); competence deficit among employees; non-recognition of human efforts; incorporation of violators of human relations, human rights, etc., in matters associated with various UN forums; complaints; general unrest; charges of corruption⁵⁶; peacekeeping violations including allegations of rape; etc.⁵⁷ Many of its programmes have either failed or did not show

⁵⁴ODA deals with the official aid policy of the concerned government to address challenges of the world including peace building.

⁵⁵“UN's Role is to Project Washington's Policy and American Power to the World.” PTI News Scan, New Delhi. 9 December 2004.

⁵⁶The Secretary General was seriously concerned about alleged corruption in the food for oil programme in Iraq during the Saddam days.

⁵⁷Zakaria, F. When UN Fails We All Do, *The Indian Express* (Mumbai), 10 December 2004, p. 7, and UN Members Back Annan with A Standing Ovation, *The Indian Express* (New Delhi), 10 December 2004, p. 7. The corruption charges against the United Nations in the oil for food programme were refuted in the report that stated the programme was designed by the United States and Britain. According to the report, they allowed Saddam Hussein to choose his trading partners, banks and consultants. They vetted every contract. The corruption scandal is a price the United Nations had to pay on an issue over which it had only an endorsement of its name, but no actual control. The US lawmakers called for Koffi Annan's resignation, but the General Assembly gave a standing ovation to him that lasted a minute. It was interpreted as an acknowledgement of his actions as the secretary general according to the Assembly President Jean Ping of Gabon.

effective results. An example is the poverty alleviation programme. Article 51 restricts the use of force to countries that have been attacked. Whether a nation has to wait to be attacked for recourse is a question. A threat has to be considered an attack and the country should have the capability to respond. Most of the time, it is not the case. Here, the question of pre-emption comes out sharp.

There is no doubt that the United Nations needs to change periodically to ensure the purpose of collectivism in global security and equity and equality among its members. It is going to take considerable time. The pace is slow. One of the reasons is that the goal human system is not a perceptive system sans a system boundary that can define it.

The prime minister of India had brought out the concerns of India in his annual address to the UN General Assembly (UNGA) for completing the necessary reforms of the United Nations and expressed apprehensions about their logical conclusion. The present state is that decision-making on important matters has been the privilege of a few and selective few. Abject disparity is visible in the world's largest decision-making body if the United Nations can be compared with other human systems as one. But this study doesn't consider the United Nations comparable to a nation being not a system similar to a nation which also accounts for its limitations where it is administered by elements that are actually larger than itself that too under a Charter that is deficient to meet the present. A nation state is superior to the United Nations until United Nations considers all of them equal. It is not possible for a very long time. The reasons to look into the reforms lie in this statement. Till then, the United Nations will work as a slippery driveway towards collective security. Associated limitations will also reflect in all its resolutions. Special attention, therefore, is necessary for the success of Agenda 2030 that is vital for the well-being of the future generations.

16.10 So, What Is Geostrategic Security?

Geostrategic security, in this study, is the eighth identified element of national security in the chronological hierarchy of 16 elements. Geostrategic security, "geosec" in short with the symbol " g_{s1} ," is about governing national security with due concern to international law and treaties and applying them to domestic laws internally with an external outlook in a geostrategic context in a responsible manner towards the well-being of the people internal and external to the country over the globe, whether citizens of the country or naturalised in other countries as the national government deems fit. Geostrategic security is closely related to the national security governance of other countries to the extent their affairs matter within their own country and includes diplomacy, geopolitics, confidence building, conflict avoidance, cooperative engagements, resource sharing, war deterrence and various other measures for collective well-being and sharing global and national commons in a responsible context of international relations through goodwill and healthy

competition with due to concern to humanity as a whole under the principle of human singularity and differentiality for mutual respect.

While geostrategic security advocates international relations for survival of the nation and its people as an element of national security, it also promotes shared values in doing so under the principle of humanity in the sapient world of the day and human advancement. This is evident in the policy of India in national governance, *Sabka sath sabka vikas aur sabka vishwas* (together with all, development for all and the trust of all).⁵⁸ While it is a thought-provoking slogan for governing the national security of India as a nation, the theme is very much extendable to the entire global human system under the spirit of shared well-being when global governance evolves slowly into a reality. Nations can emulate such principles in the true spirit and fashion of sapient life far from the tired approaches of insularism.⁵⁹

16.10.1 Definition: Geostrategic Security

Against the background of this study, geostrategic security means “*the capability of a nation to optimally balance the geostrategic context of a nation at any given time towards maximising the well-being of the people of the nation including those residing or naturalised in other countries, where geostrategic context means the interactive interface between each of the independent human system entity of the world, also called geostrategic entities, perfectly aligned with the other elements of national security and integrated with all the terrains of national governance.*”

⁵⁸Slogan coined by Narendra Damodardas Modi (1950–), the prime minister of India (May 2019). Modi coins new slogan—sabka sath, sabka vikas, sabka vishwas. Business Standard https://www.business-standard.com/article/news-ani/modi-coins-new-slogan-sabka-sath-sabka-vikas-sabka-vishwas-119052501024_1.html. Accessed 24 March 2020.

⁵⁹See Chap. 32 for the meaning of sapient life.

16.11 Summation

Geostrategic security is a worm tunnel passage⁶⁰ for a nation to enter by short process⁶¹ into the global scenario. It is executed outwardly in openness. The geostrategic security is the position of a country among the world community in a hypothetical hierarchical order, its national power, assertive bargaining capability and goodwill it has earned historically all combined along with other parameters that are still evolving. It is a variable and changes every minute depending upon the stand a government will take. It can even deviate from the original path if the steering is not proper. Often the mistakes are realised later and whispered softly and carefully. Geostrategic security is not just diplomacy. Diplomacy is the carrier vehicle of geostrategy that is not left to the foreign office alone. It is also important to understand that geostrategy cannot be outsourced. It will be a costly mistake.

One of the dissatisfying tones of geostrategy is when nations comment belligerently about conflicts to satisfy the public in their false ability to ingratiate in misadventures of conflicts with the neighbours or others further across. Comments that focus on dialogue for settlement of issues and development of cross-border well-being will go a long way in strengthening geostrategic security as opposed to threatening language mainly aimed at playing to the gallery of word-hungry mobs. Chest beating on the use of force is not normally welcome in such scenarios and will further debilitate a nation's geostrategic capability and wipe out the goodwill that would have already earned under stringent conditions by generations in the past.

There is no place for individual ideologies or fantasies in geostrategic security. Influence from powerful lobbies can affect and turn the course of geostrategy. Some such turns may show comfort initially. Often, such comforts are short lived. Geostrategic security is strictly based on win-win situations and in the long term in a win-hold-win approach. There is no alternative to that. The geostrategists in national security should see the world the way it is or would be, not the way it has to be. They have to manoeuvre within that.

The United Nations is yet to go through the acid tests that can assure its survival. In the meantime, recommendations of the review panel raise issues that may be questioned by the powerful directly or through proxy. In that case, reforms may not come through; but the United Nations will still stand and may not decay like the League of Nations. There is a win-win situation here for the secretary general and his team. The political shockwaves were there even before the 2003 Iraq War. The fault

⁶⁰The expressions "worm tunnel" and "worm tunnel passage," though borrowed from cosmology for specific reasons by the author (not explained), import different meanings. The worm tunnel, as used in expressing the togetherness in singularity of humans as a unitary civilisation, is fixed relative to the human system as a static dimension of expression and moves (normally forward as seen so far in a surging fashion) along with the human evolutionary process and may even extend to a deep space when sapiens colonise other space bodies one day.

⁶¹Short process in governance means the most appropriate and hence the fastest means by which a nation can extend its governance into another dimension beyond the boundaries of a nation or national concept.

lines were seen decades ago once the post Cold War brought fissures in erstwhile Soviet Union and its eastern bloc allies. The United Nations became a mute witness rather than an astute suppressor of aggressive dogmas of national disintegration. The recommendations of the panel may give a new lease of life to the United Nations. Otherwise, the world may have to wait for another world war of assured mutual destruction for a more credible world organisation. The United Nations stands for hope; but with the United States selling it a dummy at all times, it could be a false hope that the United Nations promises. The geostrategic equations of the nation states of the world do not focus on this issue. The world may be on a long wait for a more credible international organisation.

Deception in geostrategy can be seen, through biomodeling, as an ingredient that could be well done away with. It is more damaging to the perpetrator even in the short run. Worst, the confidence gets shattered and it will be difficult for generations to build it up later.

The hypothesis that the world will be monocentric with the superpower turning into superstate at the top of the hierarchy of nations is for the beholder to visualise and debate. According to certain theorists, the Cold War is still simmering. It does not seem to be correct, because the equation of the foes has changed. One is eliminated and vanished from the map. The other has converted itself to a superstate. The competition will be between the prospective superstates and with the superstate after a certain period. That perhaps may lead to another Cold War, though chances are meek since the competition among the prospectives will continue. The superstate will be struggling to hold to the position in the meantime. The 2004 Ukraine elections place the lid firmly on the perception of the issues. The pro-western candidate Victor Yushchenko won in reelection. The Russian backed candidate Victor Yanukovich's lost. The world looked at the two candidates as proxies of the United States and Russia, respectively.⁶² The superstate should be careful about a geostrategic burnout by involvement. There are two key areas for the United States—Iraq and Afghanistan. In both these countries, the American forces are involved widely in maintaining balance. But the situation is extremely fragile. Similar situations may come up in the future. The psycho-econo-geostrategic burn-out of the superstate starts from such situations. It is not just supporting the cost of war and counter war but also the cost of entanglement with the weak that in turn weakens the powerful. This means continuous drain out of geostrategic outputs, and therefore, the cost–benefit analysis is part of an audit for the superstate. The benefits have to be extremely high. The decline will set in if it is on deficit. Geostrategic status of a superstate is not governed by the weaknesses of its nearest challenger, but that of its own deficit in holding on to the top.

The world was never certain; therefore, uncertainty is not an excuse in geostrategy.

17.1 Introduction

First, it is important that the term “information” is understood by those who use it in expressive communication. Information is an uncountable term. It is not communication per se but what is conveyed through open or closed communication. Thus, information is the resolution perceptively refined from acquired data and transmitted deliberately or commonly in the open or an enclosed human system as appreciated by the sender or originator for action. Ideally, information should move from sender to receptor without loss or distortion enroute. Factually, information will suffer loss or get distorted. In this study, information contains all those knowledge matters involved in governing by national security.

There are differences between communication and information. Communication is an act of delivering information or conveying a message by the sender to the receptor. The process has its own difficulties. It started with God.¹ Perhaps God messed up human communication, thinking people will be able to manage it themselves as a survival task. When early humans got embroiled in egoistic intellectual orgasms, they felt they should also get the comforts of God. They tried to reach God's domain supposed to be in the sky (hell is underground, for the less of the non-mortals and the bad among the mortal humans, something similar to below poverty line through which politicians siphon off funds in some systems) and share it by constructing a tower. God, who knows everything, simply cursed them in own language that when translated read something like this: "From now on you guys are not gonna savvy what the other says," or rather "Now on dopeys, you ain't gonna grab what others pitch." That meant the works manager won't understand what the foreman says, foreman won't understand the supervisor who will not understand the worker, and vice versa. That meant, in productive language, the input for manufacturing a car will come out producing a truck at the end of the process line if one depends only on the data passed along the line. No wonder the twin towers were missiled by commercial aeroplanes; originally, the targets would have been the bridges across the Hudson, perhaps, or the distant Golden Bridge. Who knows? God's curse, pronto. It applies to anteforces also. Whatever, since then, inter-human communication got clogged and distorted among humans like the sewage pipes in some metros. Animals do not have this problem. They didn't dare to make the tower. So now the father monkey can warn its lad monkey or the neighbourhood deer flock when the big bad cat moves around, without any distortion from the usual vantage point, the trunk up the tree. They do it well. They won't need this book.

Humans could not complete the tower to reach God. How could they? No one understood anyone. The work was abandoned. Bingo, God had His say. He went golfing to Camp whatever. Humans call God at critical moments, "Oh, God!" in every language on the planet. That's communication. Information is not exactly communication. The curse of God is on communication in the Old Testament,² not information. Humans are lucky that way. But the fact is information need to be communicated to make decisions.

¹Invoked God to drive home the meaning of information. God comes in three forms (author): God, gods and no god. ("No, Oh God!" is not a god.) It also means there is God for every human who is sentient and senile. God balances the mind of the knower (the one who knows God at least in one of the three forms) to a great extent. As per this study, god exists as an abstraction—neither real nor unreal—and is strictly personal. This statement here is not based on any religion or other belief system.

²Wikipedia. Tower of Babel. The tower called the Tower of Babel is narrated in [Genesis 11:1–9](#) is meant to explain why the world's peoples speak different languages. This is used by scholars to explain communication and its barriers in the right perspective. https://en.wikipedia.org/wiki/Tower_of_Babel. Accessed 20 January 2020.

Information is explained in different ways. One is to say information is knowledge without any sort of semantic aberration³ when communicated. It is also not intelligence.⁴ Information security is about managing information optimally as an element of national security. Governance cannot function without information. Decision-making demands it. Certainty prevails when information is complete for a particular decision problem. Information is uncorrupted knowledge, but it has different meanings in different contexts. In national security studies and governance, information is the clear, correct and unblemished knowledge that is right and impacts governance causing change in the overall maximisation process of national security. The term, information, is also associated with cyber operations and various other activities. The element, informational security, deals with information—the subject of knowledge—and knowledge acquisition, retention and communication. Knowledge is a collection of facts or data on existing or new things gained by erudition and experience. Knowledge is derived from information after testing and accepting truth from facts derived from data. Knowledge is disseminated every moment in all aspects of national security governance in a human system. The world has advanced by knowledge to the extent that the humans have already entered the epoch of knowledge. That is the impression generated from the oft-repeated statement—the knowledge world. If the statement is factual, then the world has stepped into an age that is not going to only remain as a knowledge world but also expand as a knowledge vista or universe. Mathematically, a knowledge world cannot reverse to the dark age of ignorance. It is much beyond the renaissance period or any other stages of intellectual transformation in history. If intellect is the survival tool of the sapiens, then knowledge keeps its cutting edge honed progressively. Knowledge grinding prevents the survival tool from getting blunt. This also means knowledge is meant for survival through sustainability, not destructive manoeuvres, though it could happen as the process of survival is by any means. It is not exclusive to humans. The process of survival is similar to all life forms. They use their respective survival tools. For humans, it originates from knowledge which, in turn, is processed from information.

Information helps people to define their attitudes towards their existence. It is on and has passed many stages in human evolution unlike other life forms. Human evolution has witnessed so many intellectual escapades inviting apocalypse enroute by the application of knowledge that too primarily processed by defective information. Knowledge is an ocean and the humans have reached its shores in the new century. They are yet to enter it as this study finds. They appreciate its importance for reaching out to a sustainable new world adapting to exemplars of human understanding. Today, people “want to know” wherever they are located. Knowledge acquisition has become the most widely pursued objective to understand a subject or

³Semantic aberrations can be any deformation of information when it passes through a barrier to a receiver: incorrectness, dissonance (where sender’s meaning is not understood by the receiver) (Chap. 1), incorrectness, communication incompatibility and so on).

⁴Explained later in the chapter.

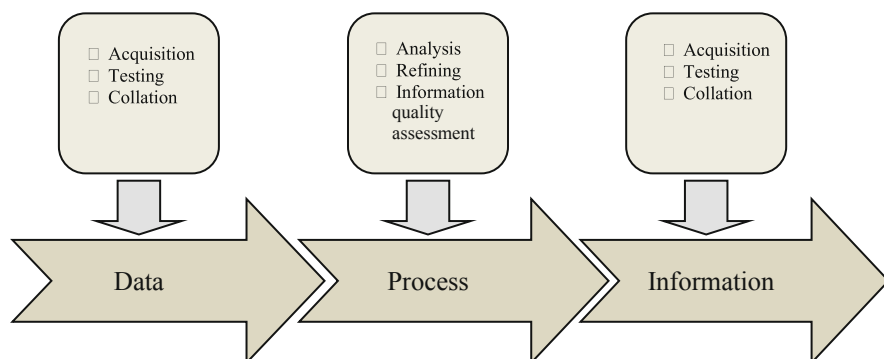

Fig. 17.1 Data processing for information

topic factually and in actuality. It is the state of knowing correctly. It is the range of correct perception of a subject or topic that matters to the individual and society. In the knowledge world, informational security is an element by itself for these reasons. It comes in different forms. Data holds the key for information. Data is the game changer in informational security. Therefore, data has to be acquired and collated with utmost care and efficiency.

Information refined and extracted from data, therefore, is valuable knowledge that is right, needed and timely, specific and organised for a purpose, presented within a context that gives it meaning and relevance, compatible for effective communication and ultimately supportive to decision-making in a human system (Fig. 17.1).

Information is valuable because it can affect behaviour, a decision or an outcome. It is considered worthless if it is not useful for decision-making. What a government requires for governance is an absolute governance information system (GIS) for establishing total informational security.

17.2 Informational Security: Setting

Informational security, as an element of national security, is the discipline that deals with the processes of storing and transferring information related to a system—a country, within the concept of national security. It is also applicable to other human systems for governance, such as a corporate system, where the focus will be on the business policies and decision-making.

In national security, information brings together concepts, methods and intelligence from various disciplines of politics, governance, security, national polices, diplomacy, research and development, military, etc., through aids that handle acquisition, collation, recording, organisation, storage, retrieval, interpretation, display, dissemination and use. Information is documented for communication and transmission. There are many acquisition, storage and transfer media through which

information is gathered and transmitted continuously in the knowledge world today. The world will stop functioning without information feed because every system relies on information.

Information is linked to people participation in national security. People have a right to information because they are not just stakeholders but also partners in governance. The modern-day governance is based on this fact—the right of people to information and the responsibility of government in providing such information as necessary for national security governance. Kautilya's *Arthasasthra* places great emphasis on the importance of information and its correct dissemination through a network of runners, informers and spies, which, in the absence of a ministry of public information and a police force, functioned as a surveillance corps for the king, focusing particularly on any external threats and internal dissidence,⁵ and so were the contemporary political and strategic advocates. In its modern concept, information is much beyond the realms of any discipline within limited boundaries. In popular usage, the term information refers to facts and opinions provided and received during the course of daily life. Information is received from various sources. The received information further generates information. Information organised in logical relationships becomes knowledge to be acquired by systematic exposure or study. Application of knowledge yields expertise. Analytic insights into the information lead to wisdom. Information permeates the country's national security elements and has absolute interactive geometry with all the other elements. There is a profundity in the transformation of society and culture as a continuous process. The societal changes that become visible tomorrow are by the processes that actually take place today. It is moulded by information.

The process that caused the change the humans witness today had started much earlier, especially in science. The changes are a combination of successive events. Here, the way people think is important. Individual and collective value systems are different from that of organisations, government and other compound institutions that often think in the Cartesian way.⁶ Cartesian thinking does not pave way for most of the changes that take place because it was based more on introspection than innovative thinking. This study respects but does not support Cartesian ways—thinking process and dualism of the body–mind concept evinced by René Descartes in seventeenth century. Information is shaped primarily the way the mind perceives

⁵Encyclopaedia Britannica, Ultimate Reference Suite, 2004, CD-ROM.

⁶Latin Rene Descartes (1596–1650) was a French mathematician, scientist and philosopher who studied law in the beginning. He was one of the first to oppose scholastic Aristotelianism. His forte lay in doubting knowledge based on authority, the senses and reason and then found certainty in the intuition that *when he is thinking, he exists*. His famous statement “*I think, so I exist*”—the famous *Cogito ergo sum*, or *Je pense donc je suis*, explains his view of existence. He developed a dualistic system in which he distinguished radically between the mind, the essence of which is thinking, and matter, the essence of which is extension in three dimensions—metaphysical (the root), physics (the trunk) and sciences (the branches). Descartes' metaphysical system is intuitionist, derived by reason from innate ideas, but his physics and physiology, based on sensory knowledge, are mechanistic and empiricist.

it, which is based on innovation at all levels and instances. Even a rumour—rumour is data (data of any kind contains information)—is innovative. It can be wrong if the mind does not perceive it correctly. It often happens in a system where there are many who think on a singular topic differently. Information, therefore, gets into a flux if not managed correctly.

Philosophically, information is considered an objective (mind-independent) entity.⁷ It is applicable in information theory related to communication. Informational security deals with information generated by mind. Information in a human system applicable to that system is generated by thought process of the people involved. Odysseus could not have fallen upon the idea of the Trojan horse without consistently thinking about a plan for a deceptive tactical coup in the legendary war against Troy.

Interest in information phenomena, the way it is defined in this book, increased dramatically in the twentieth century.⁸ Every government, international organisation, industry, business house, other human systems and individual is increasingly generating information and is concerned about information gathering and security. The often-overlapping viewpoints in these fields lead to different (and sometimes conflicting) concepts and “definitions” of information. It warps the informational security related to such systems. Beyond such distortions, it is processing data for information that becomes a concern of informational security. Information is knowledge about anything which actually is data misconceived. Data is in crude form. It needs to be refined for information. Information is a processed data for decision-making. According to some viewpoints, even the unprocessed data is information but needs to be refined and processed prior to decision-making for effectiveness.

A major issue here is how to know the information is actually information and not data misconceived? One way is for the government or the decision-maker to decide whether it needs further processing or not. In most cases, it will require processing. Restructuring information is done by decision-makers—government, corporates, citizen groups and various other human networks. But for information to become part of the collective consciousness of the people of a country, it has to be transmitted through relevant media. It will be a mass media if information is aimed at the people in general or a select media if aimed at a select section of the group.

Information may get censored before communicated. While it may be needed for specific reasons, censored information will lack continuity. The gaps will show. They get filled by additional information originated in the minds of the receptors. Such issues will invoke people’s right to information in national matters. It is an important aspect of social change.⁹ Mass media becomes important here. There is a lot the mass media can do in governing the element of informational security. The types of information in national security can be those connected with governance,

⁷Audi, R. (ed.) (1999). *The Cambridge Dictionary of Philosophy*. The Cambridge University Press. p. 435.

military, research and development and all other factors that govern each of the national security elements. Considering that the government and the people have mutual responsibility in national security maximisation, information should be secured for its correctness and user limitations. Often it is not possible and, therefore, not done. Informational security calls for restructuring of information flow patterns to make it effective in national security management.

17.3 Securing Information

Information originates every moment at every point in the working of a nation. Information is an important collective entity for governance of national interests. Any lacuna in the system of information management will be showing in the ultimate national security audit. Informational security, therefore, is very much an element of national security and equally vital for its maximisation like other elements. It has to be legislatively protective of state secrecy. Information that affects a nation's sovereignty, integrity, elements of national security, scientific or economic interest, conduct of international relations, internal notings on files, etc. are to be reserved and secured if they are likely to hamper national security.

The opposite is the citizen's rights for disclosure of information. These rights may strike a discord with national security objectives if not balanced properly. Anteforces can exploit people's rights. The free system with a high-profile free media can be loud. Human right laws may call for certain amount of liberalisation under natural justice. The government has to have a say in informational security in a balanced manner and appropriate to national interests. These are to be cleared and clarified through enactments. They are people-oriented activities related to freedom of information in the governance of a nation.

Most nations introduced freedom of information laws that mandate them to disclose certain data to the general public upon request. Sweden was the first to introduce such laws as Freedom of the Press Act, 1766. It established press freedom.

India introduced the Freedom of Information Act as early as in 2002¹⁰ after serious deliberations. It was based on the recommendations of the chief ministers of

¹⁰Raina, J. "Right to Information Gets LS Vote." *Hindustan Times*, New Delhi. 12 May 2005, pp. 1–16. India's Lok Sabha (Lower House) passed the Right to Information Bill on 11 May 2005. It will be path breaking and provides for a framework for making citizens right to information a fundamental right under Article 19 of the Constitution of India. Once it becomes the law, it will pave way for the setting up of a Central Information Commission and similar outfits to provide information to the people. Information as defined in Clause 2 (c) of the proposed law comprises "any material in any form including records, documents, memos, e-mails, opinions, archives, press releases, circulars, orders, logbooks, contracts, reports, papers, samples, models, data material held in any electronic form..." The law will empower the citizen the right to inspection of work, documents, records, taking notes, extracts or certified copies of documents or records, taking samples of certified material and also information in the form of diskettes, floppies, tapes, video cassettes or any other electronic mode or through printouts, etc.

Indian states in a conference held on 24 May 1997 on the subject of effective and responsive government.¹¹ The Act provided for freedom to every citizen of India to secure access to information under the control of public authorities, consistent with public interest, in order to promote openness, transparency and accountability in administration and in relation to matters connected therewith on incidentals thereto.¹²

Right to information to people is largely exercised through the free media in an ideal setup. Information flows through media. India has good records about the media involvement in information flow. It was the media who brought out information about a little-known village Kot Kapura, in the state of Rajasthan, India. They exposed the huge corruption involved in development and poverty alleviation projects. They contrasted official records with reality on the ground. Every villager who was present got up to contradict official statements. The fraud was proved beyond doubt by sheer information and media support to correct information. It was on a public hearing organised to demand right to information. The people want access to information concerning them and they do not want the governments to hide it under pseudo excuses. This right was conceded, backed by legislation.¹³ It came from the government's realisation that the people have a right to information. Public access to information can help not only corruption, which is a serious menace to development, but also people participation, a much-needed support for governing towards NS_{max} .

Freedom of information does not provide the right to a person to demand all information connected with the state. Informational security does not permit information that if made public can cause serious harm to the state be made open to the seeker. These are the information that may prejudicially affect the elements of national security if made open. Similarly, there is information that would affect the concept of NS_{max} if not made public. Informational security, therefore, is managing and regulating information flow. Legislative measures on freedom of information and informational security should be adequately clear on this subject.

In India, according to Public Records Act, government records, once they become 30 years old, should not only be transferred to the National Archives but also be made available to bona fide researchers. Many countries have a 30-year rule for making public the sensitive documents.¹⁴ Such a procedure could give transparency of governance. According to S. N. Prasad, the retired director of historical section of India's Ministry of Defence, publishing war histories in time would make considerable significance in the national security scenario. There is abysmal ignorance about such things in parliament debates. Parliamentarians in 1962 reportedly coerced and forced Nehru, the then prime minister of India, to take a military posture against

¹¹The statement "effective and responsive government" is important here. National security needs effective, responsive and responsible governance.

¹²*The Freedom of Information Act 2002*. Law Publishers Pvt. Ltd. p. v.

China. It was untenable and led to the Chinese attack according to him.¹⁵ Prasad also stated that public ignorance could be at the root of failure to achieve the best military results according to him.¹⁶ Informational security is not safeguarding information alone. It also has to take care of information overload and misinformation based on psychological operations (PSYOPS) and information warfare whether covert or overt. The capabilities far exceed their requirements today. Snooping on radio stations and controlling them by those who are generally known as “the pirates of the airways” through carefully programmed frequencies will turn to pale when the latest experiments on mind control drop a lid to exhibit its perceived potential. Its implications are chillingly real. It can control people, the whole population, and, according to analysts, could already been happening. There are also predictions that mind control will be the most non-lethal weapon that will replace all other smart and lethal weapons. According to the Discovery Channel in 2001,¹⁷ “War-2020 may be the one without so much of a whimper.”¹⁸ But it didn’t happen that way in 2020 which is already over. Millions of prophesies go off the shoot without a whimper with money spinning on their names. Nostradamus is one. Was he there or was it a clever idea of see-through business? Seeing through time is possible but humans are yet to get the hang of it clearly. While so much has been said on mind control, one could also give it a cushion from the past quoting the experiments of the Cold War days on psychokinesis, telepathy and other paranormal mind games conducted in secret human laboratories of the then ruling superpowers of the world over land, air and sea (in surface vessels and submarines). These experiments that vanished without a snivel are another matter, though. But UFOs and Bermudas still refuse to vanish.

People, all over the world, want to be informed. A letter to the editor, *Navhind Times*, a newspaper published from Goa, India, demands the Department of Information and Publicity of the Government of India to inform the people correctly and periodically about the development work undertaken instead of allowing them to gather information that trickles down from assembly sessions.¹⁹ Another way to express this demand is calling for transparency in public dealings. But it is strictly the craving for right to information in the minds of the people. This indicates people’s interest in public affairs and the balance required for informational security by exposure and containment at the same time.

An integral part of informational security is knowledge management at a national level. Knowledge management is defined as the “capability to generate new knowledge, disseminate it where necessary and embody it in its system” with respect to

¹⁵Manoj, J. “War with History, Interview with S.N. Prasad.” *Times of India*, New Delhi. 25 September 2000, p. 10.

¹⁶Ibid.

¹⁷“Beyond.” *Discovery Channel*. 12 March 2001.

¹⁸But it was not so when seen from the new elevation of 2020. (Also see Chap. 9.)

¹⁹Khandeparker, B. G. “Keeping the People Informed. Letter to Editor.” *The Navhind Times*, Goa. 24 August 2001. p. 8.

national security. It is applied in all walks of life, but at the national level, it has to be associated with maximising national security. The knowledge can be subjective (tacit) or objective (explicit). It brings together strands from various disciplines and technologies. An example of independent informational security where knowledge management is effectively used is the knowledge-enabled electronic governance in certain segments of society including national organisations and communities. The regulated data that flows through the corridors of governance should be accessible to all.²⁰ Based on registration records with the registrar of Newspapers, 1,05,443 newspapers and periodicals were published from India as on 31 March 2015. Over 240 million copies of newspapers circulate daily in India.²¹ There are also comments that all those registered may not be printed. In other words, the purpose of such registrations need not be information dissemination of any kind.²²

The press can influence the public. Therefore, those interested depend heavily on it. On the whole, the press in India functions with little government censorship. Radio began privately in 1927 in the United States and became the monopoly of the state in 1930. Television was introduced in 1959 and regular broadcasting commenced in 1965.²³ In India, there are rules of fairness that makes the opposition views to be heard. The media is a powerful information source. It has the potential to become a regulatory source and can be effectively managed for informational security. Informational security with freedom of the media is the hallmark of any nation's system of governance aimed at NS_{max}.

An issue that causes concern among researchers studying changes in society is the growing gap between the information rich and the information poor. Information rich are the people with easy access to information. Information poor are those with less access to information. This difference can cause information equality and percolate into decision imbalance in society.

There are two types of information relative to a system: (1) the knowledge that is wanted from outside the system and (2) the knowledge that is originated within the system. Both are required to be protected for various reasons within a particular time span. The security of information and its effects on national security depend on the nature of information and the way it has been handled. Here, there is a similarity with cyber system information management—audit of information, zero-leak, preventing information corruption, etc.

In national security management, information leak and distortion can cause heavy embarrassment to the government. The prime minister or president may find his

²³Encyclopaedia Britannica, 2001, CD-ROM.

colleagues dropping policy decisions into the media basket without even consulting them. There are cases when the prime ministers have read about a new policy from the newspapers rather than the concerned originator seeking permission from him and then issuing strictures.²⁴ There are also deliberate leaks of information as a countermeasure for toppling a move that otherwise cannot be objected to. This happens in international relations when a country cannot negate the offer of another country for a compromise discussion on disputes but can deliberately sabotage it by leaking information to the willing media who is always looking for novelty to market itself. Controversy and distorted information could be market savvy at times under competition. There is informational security coupled with media ethics hidden in this. Such leaks can dog other efforts to bring in a consensus in the conflict resolution. Often, it is not to happen when informational security is mismanaged or deliberately turned around. This is also a matter of concern in geostrategic security.

17.4 History: Information That Was and Would Have Been

Another class of information is what originates from the so-called exploratory studies of history and recorded in genuine documents of all varieties including those in time capsules kept underground or vaults for future generations or messages sent to aliens presumably friendly with the confused souls on Earth. Unfortunately, history often doesn't speak the truth. Practically, it is impossible to record past in the absence of truthful information sans prejudices and integrity of purpose of recording. It is therefore necessary to consider history a hypothesis at any time in the minds of anybody and tested on every occasion before decision-making. Decisions can also be taken based on accepted information by those affected by it. The truth gets distorted, sometimes deliberately, in historical recording. History should not be brewed or prepared; it is the record of true events happened in the past. Here, decision-makers have a choice: to consider information as only truthful information or any information as information until corrected or accepted for processing and making decisions. Impure information is dark information coming out of dark knowledge. So, ultimately, any information that is accepted by the human system for decision-making is information in the present. That explains the apparent security-perceived security combo in national security. Well-being is a perception of humans based on information alleged and accepted.

National histories can be distorted ignorantly or intentionally. Historical information will turn out to be what the informers want to convey or do not know. Historical information could be wrong *ab initio*. Distortions might also occur for various reasons including unawareness and lack of feel atypical to alien observations

²⁴ Sharma, V. "Don't Surprise Me, PM Tells Ministers." *Hindustan Times*, New Delhi. 12 September 2004, p. 1.

of a system. Restructuring these misreported historical records today will cause problems of political and intellectual nature. Therefore, history will remain as mute witness of its own disfigurement. It is common all over. Histories of Pakistan and India on the same issues are reported and taught in schools differently. The colonial rulers have already distorted them and the subsequent generations have further twisted the distortions and rung them dry of even traces of truth based on vested interests. The problem with distorted information is that it gets further elongated by distortion in time like Pinocchio's nose. It doesn't get shortened by telling the truth. They will be further confused by subsequent writers. There is no system to test information accuracy either with the government or public. Correcting can bend them further. The information that was thus undergoes serious misrepresentations continuously in repeated parodies. A sincere effort to re-record the history of a nation or information that was, therefore, is extremely difficult. Some nations may attempt it but have to be careful not to distort further. Rewriting history in its original form even by acceptable research will be virtually impossible. Historical information once damaged is like a bowl of jelly smashed under a truck. The maximum one can do is to scrape it out. What does that mean historically? It means any history is worth to make history because of information misrepresentation. There could be counter points on this statement that need to be respected, though.

There are many such recordings of information that are available in the annals of history and passages of information corridors. Even a mention in this book could be controversial. Handling such information is another aspect of informational security. The best way is to avoid debates that may fan factional disturbances and conflicts to avoid damage in national security fabric. Besides, it is a fact that the way information is distorted in history is the way those who distorted it wanted history to be. History was never in the making. It is actually made thereafter. History is the epitaph on tombstone of time that passed away. Normally, epitaphs are not written by the dead in the dead of the night, but by those still alive in the broad daylight. History is written every moment when time dies. Information spills every moment it is written and gets frozen immediately. Distortion of information is a kind of wish fulfillment. But it affects knowledge generation and retention very seriously. From the informational security point of view, misreported history or the information that was may be best left that way without repetition or serious indulgence to avoid further distortion. It is a better choice in a more civilised world that takes the element of informational security seriously.

One of the tendencies in a human system is to dangle with information in a vacuum. This tendency is projected when information that was not there is reported knowingly and analysed to counter realistic information. The originator knows well that the information is casual by its non-existence. In this case, the originator analyses history, not the way it happened or reported but speculating the way it would have been with leading statements or questions that are hypothetical. It is also important to mention here that this study doesn't support any information that starts with the "would have been" clause as evolutionary activities are in a straight line or in directions similar to the inkblot without disruption except for alteration of courses

as if on an imaginary gradient which humans may consider chance at his stage. The heading of an action when changed by alteration of course shifts to a new direction. It is not spatial. It is relative to time, hence time functional. The previous destination gets deleted by overwriting of new destination. Hence, information becomes time functional and happenings along the course of evolution. This also counters the idea of trade-offs in any action post alteration of course.

Historians are supposed to record the past strictly based on truth from facts. For that, they have to know the facts and should have the conviction to record them. Somebody stated that Winston Churchill²⁵ was a heavy smoker since he was always seen with a cigar in his mouth.²⁶ But there is also a statement that the cigar in his mouth was only a kind of his personality brand projection. To which statement does one say, Aye? He lived quite long. Is there a clue in that? Is it necessary to depend upon secondary information when first-hand information could be recorded? Distortion effaces information. Are methods of distortion clean-up identical to deliberate and accidental distortions in informational security management? Another problem is in deciding which informational priority for recording. Churchill's cigar gained informational priority years later in his elite behaviour and associated props.

People starve for information. Ironically, the urge is to talk and not to listen. They behave strangely to the opportunities of information flow. In Andhra Pradesh, India, the state where drought drives peasants to commit suicide, there appeared some water in some village wells far away from the sea. Immediate reactions of the people, including that of the scientists who should know, were bizarre. The scientists were faster than others to talk it out. They attributed the find to the tsunami that had hit the southern and southeastern coastline of India months back. There was no verification of the cause. The commoners were more rationale with respect to their reactions. They stuck to their belief systems. According to them, it was a godsend and they performed divine rites and gratification rituals to please the gods. They resorted to spiritual security measures when the government could not provide them apparent information. Even for the all-knowing media, it was "mystery" water that came up in the wells.²⁷ Information is distorted at will.

Non-informational statements and questions are sorts of rhetoric aberrations and, therefore, best done when not repeated. Informational security opens a new niche for these types of information, "*don't talk; don't ask; don't answer.*" It depends on the enlightened knowledge of the citizen and his concern for national security. The government's role is not repeating such understandably distorted historical information, to retain the facts in day-to-day functioning of the nations and never to rake the "what if" questions. Such conduct is also equally applicable to the citizens and the

²⁵ Sir Winston Leonard Spencer Churchill (1874–1965). British prime minister (1940–1945 and 1951–1955) and writer who won the Nobel Prize for literature (1953).

media, though often not followed for obvious reasons. In such cases, it is the job of the government to contain the effects of such information under the element of informational security.

17.5 Information and Intelligence

Information and intelligence are widely used terms in human system communications. Intelligence is information in a specific attribute about the “other party” and its intentions in a competitive environment. Usually intelligence will be actionable information. It comes out of refined information which, in turn, is refined data. The environment in national security maximisation will always be competitive and challenging. Intelligence is an integral part of this challenge. Mere information may not lead to required action. It needs intelligence. Intelligence could be derived from information acquired and collated under constant information surveillance.

Intelligence is classified in varied ways. One is to classify as strategic, tactical, operational and counterintelligence. The broadest of all is strategic intelligence, whereas most of the actionable intelligence falls in tactical, operational and counterintelligence. Strategic intelligence will primarily contain information about other parties. This information will be about their capabilities and how these capabilities can jeopardise the national security objectives of one’s own country. The difference between tactical and operational intelligence is quite narrow. Tactical intelligence leads to operational or combat intelligence. Both are information required by field commanders and operators in the concerned fields in military security. Such information is not restricted to military alone but also governments and other institutions for their manoeuvres in every field of national security. Intelligence narrows down through tactical intelligence to operational intelligence. Even the distinction between strategic and tactical may be vanishing slowly because of the advancements in intelligence acquisition, collation, analysis and dissemination.

Counterintelligence is of different kind. It is information and activity related to protecting one’s own information and the secrecy of one’s own intelligence operations. Its purpose is to prevent agents or intelligence mechanisms of other party from penetrating own information and information assets. Counterintelligence is also concerned with protecting a nation’s high technology, deterring terrorism and coping with transnational crimes and so on. Counterintelligence operations sometimes produce positive actionable intelligence. In counterintelligence, a fairly good idea about the movements of the adversary is required to understand the kind of information that is likely to be tapped. In addition, there is a need to understand the capabilities of the adversary along with the likely methods that will be used to acquire intelligence.

Intelligence is part of maintaining own informational security and breaking that of the adversary. The public perception of intelligence is that of a cloak-and-dagger game, which it is not. It is simply information acquisition and safeguard. Often, it is done in the normal demeanour of an active and unassuming analyst in a quiet office.

Not all intelligence gathering is undramatic. Physical efforts are required in certain areas including normal espionage along with the aspects of cultivating assets for information. Covert sources of intelligence are dramatic, falling generally into three major classifications: aerial and space reconnaissance, electronic eavesdropping and code breaking and the secret agent working at the classic spy trade. Broadly speaking, the value of each as a source of crucial information is probably in descending order as listed. This is because a photograph constitutes hard (reliable) intelligence, whereas the report of a secret agent may be speculative and difficult to prove and therefore soft.

Intelligence is vital in any activity statement or task assignment. At the same time, it is not an end by itself. It is the other side of informational security. Intelligence is used to leverage operations. Intelligence provides intentions and near-real-time information that is collected mainly from electronic media or human intelligence including open-source intelligence and analysed for action. The key elements are setting priorities for collection, processing and exploiting the collected information and communicating results to the appropriate levels of operational or executive command. For example, taking an aerial picture is not an end; it must be analysed and communicated in a way that is both useful and usable. Otherwise, it is only information, not intelligence.

In the real sense, intelligence is information about intention, therefore functional to time. It is not a mere unrefined information or news. Information may provide a base for analysis. An intention will have certain time span. It may vary when the intention is delayed or changed. Here, it is important to understand that a changed intention is another intention, therefore another input of intelligence, the previous intention being concluded. Irrespective of the time span, an intention is actionable intelligence. Intelligence is the *hors d'oeuvre* of a craving armed force or a governance system including that of corporate governance that has the capability for action. If the intention is known, the threat-to-target time can be interrupted. It is called actionable intelligence. Actionable intelligence also serves as the big morale booster for personnel of an armed force when trapped between duty and death. The importance of intelligence should never be underestimated under such situations.²⁸

The first step in information gathering and intelligence activities is data acquisition and information refining. Collation and analysis of information may yield intelligence. Dissemination of intelligence for action is the next step. Gathering information is of no use if it cannot be converted into effective intelligence for action. It was reported that 120,000 h of data on tape was with the Federal Bureau of Investigation (FBI) in three years' time since the tragedy of terror on 11 September 2001 in the United States.²⁹ Information overload is a problem in intelligence. It can be regulated by data control.

²⁸Paleri, P. (2004). *Role of the Cost Guard in the Maritime Security of India*. Knowledge World, pp. 73–74.

²⁹“Terror Tapes overwhelm FBI.” *Hindustan Times*, New Delhi. 23 September 2004. p. 23.

One of the means of intelligence gathering is open-source intelligence. It does not need large organisational setup or costly facilities. The ability of intelligence to provide commanders with knowledge about the disposition and movement of enemy forces is part of the highly acclaimed revolution in military affairs (RMA). RMA provides an edge in conventional military operations for the foreseeable future. It is equally applicable in non-military scenario. In today's scenario, any type of intelligence spills over the capability of any single intelligence agency. Security of a people is better served by integrating intelligence of different agencies rather than allowing each agency to consolidate its turf. This is the most talked about problem. On one hand, single agency cannot do it all; on the other, more than one agency, it is said, could induce turf problems and dilution. In reality, intelligence sharing between agencies should be done under extreme caution because, if not done properly, it can dilute the whole effort. Informational security will be jeopardised. This is the reason behind the hesitance of an intelligence agency to share intelligence with another. It is not really a turf problem, though considered so worldwide. Intelligence agencies normally get the blame for the lack of coordination and reluctance in sharing intelligence when something undesired happens.³⁰ But it arises from the issue of states keeping its information tight lipped from those interested to know.

In intelligence, there is always the debate: "What is intelligence: information or intention?" All information need not be intelligence and all information released also need not be factual. Espionage and intelligence gathering are part of strategic and tactical planning since the early days. Sun Tzu, Kautilya and others considered intelligence gathering as strong points of kingdoms. The argument whether intelligence is intention, information or both can be answered if we consider informational security as an element of national security. Information that affects national security including intentions can be seen here as intelligence. Therefore, there is a need to retain such information.

17.6 Rumours and Informational Security

In any society, whether it is a nation or an organisation, the rumour mill churns all the time. It arises from the simple behaviour pattern of searching for an identity in an interaction unless there is a deliberate plan to plant a rumour. For an immediate identity in a group, the best option is to say something that the other has not heard before. It triggers the grapevine through which the rumour flows. Grapevine twirls along even in the heart of organised and secretive intelligence machinery. A rumour is usually an unverified and unconfirmed report with difficulties in tracing its origin. But communication by reversal can identify most of the grapevine originations. In fact, it could be a method used in communication where in the original text is

³⁰Paleri, P. (2004) *Role of the cost guard in the maritime Security of India*. Knowledge World. pp. 73–74.

modified in such a way that the end receptor receives the originally intended communication. Original item of information passed through standard means of communication gets modified by distortion in the process to the originally intended one. It is not easy but can be done. The prime aspect to take care in such information throwing is to see that if it defaults somewhere and the intended information crashes along, it should not become a barrier for decision-making. It is about avoidance of misinformation that can lead to wrong conclusions.

Official information on a subject can get caught in the web of confusion often people picking the item they like to identify with. The only way is to be alert about such misinformation. It is best done by a well-oiled public information or corporate or organisational information system supported by efficient feedback system. This is an important activity within the informational security management. Rumours can cause riots and other serious damages to a nation or community. Misinformation gains currency in a community that sways by histrionics even if it is unbelievable—like bleeding of a statue or milk vanishing when fed to a divine idol. Many ethnic riots that killed thousands of innocents were caused by fiery rumours in the past where government information was either absent or too late to correct such misinformation. Rumours are structurally embedded in riots and similar situations triggered under panic and fear.³¹

Rumours are, often, exaggerated information, if not totally false. Rumours take several forms in a promotive scenario, especially where the government is not able to take action. There are rumours that may damage a government, community or reputation. It need not be all the time ethnic oriented. Misinformation can arrive at any place. Though uninvited, it soon gains acceptance in a community, like virus in an unprotected computer system. It also multiplies and takes different shapes depending upon its transmission mode. The only solution is protection and that is part of informational security. The helplessness of the government machinery in controlling rumours is also for the reason that most of such rumours float around in the middle of social frenzy that has already induced system conflict. The law and order situation weakens; the people need not be in a mood to stop and listen. Such situations should be anticipated and pre-empted since rumours narrow options for corrective measures. Here lies the efficiency in information management.

Most of the ethnic riots in the world were based on rumours. Information deficit and information overload can cause havoc in a human system. Sometimes, they may complement each other. Rumour has a prominent role in modifying crowd behaviour. Basically, it is misperception of information and in some cases the correct perception with a deviation. In the first case, the system has to clear up the distortion, and in the second, the information needs to be distorted to control the mob frenzy. Both are important for national security. Still, there are cases where information can neither be corrected nor distorted deliberately in the interest of national security. This is more in the element of ethnic security. One such case was the deliberate massacre of Sikhs in Delhi, India, in 1984 in the aftermath of the assassination of Indira

³¹ Horowitz, D.L. (2002). *The deadly ethnic riot*. Oxford University Press. p. 74.

Gandhi, the prime minister of India, who was gunned down by two of her security personnel who were Sikhs. It was a case where information ignited a volatile opportunity for the desperados of crime.

Rumours are unverified information with anonymous sources of origins. The life of rumour is the urge of the human will to find information. Humans starve for information as if it is a life-saving resource. Under such situations, it is necessary for the government to feed the people with information to prevent the insatiable urge taking a different turn. And if it takes, the government has to find a way to deflect it away from national security mishaps. Often, it is better said than done. As distorted information, rumours can cause simple misunderstanding to gut-wrenching riots and beyond. Violence by rumour is part of life in ethnic conflicts and other riot situations. Spreading rumours is an act that has criminal intonations. It has to be countered by informational security measures. Most of the time, the rumours actually cause damage at various levels and intensity. Hindu–Muslim riots in India and the biggest clash of the communities during the partition of India have taken place on venomous rumours that whipped up social frenzy where action preceded reason.

It was not specific to India alone. Many such rumours can be spotted behind ethnic activities of violence and internal unrests in every part of the world. Containing rumours, therefore, is a major activity in informational security. The timing of the rumour gives a fairly good idea about its intention. Those in informational security affairs can understand it by careful analysis of past data, thereby predicting future occurrence. Countermeasures should be in place by then. It cannot be made just through media but carefully calculated strategy of containing rumour. The idea is to curtail the behaviour of antagonists. Preventive arrests in certain cases may help to avoid serious violence caused by rumours. Rumours are finding it difficult to sustain in today's increased multimedia savvy world, unless the media itself is the progenitor or carrier of the rumour. Rumours can invoke crowd hysteria. Some of the rumours can be wild and violent and the media generally understands handling of hearsay information under such circumstances. Rumours are too powerful that they can orient a society wrongly in its direction with appropriate emotions attached to it.

17.7 Information Flow

Information flows from where it is originated to the target recipient initially. Thereafter, it may continue further with additional information. It is an ideal situation where there is no distortion. The flow is close ended. The target recipient is to be identified. In most of the communication processes, the target, always, is the open public, and therefore, communication is generally open ended. For the media, feedbacks in the form of information are not important except to evaluate its target audience for pure commercial reasons. Often, information management is to avoid a close-ended information flow from becoming open ended. Close-ended information

is for select recipients. If such information becomes open ended, it is said that there is a leak in the flow of information.

The patterns of information flow give an indication of the informational security system prevalent. In a close-ended system, information flows vertical, horizontal and down. In an open-ended system, it is generic. The flow of information in both the systems will depend upon the hierarchical planning model of the state. In a network state, there will be unhindered information exchange among various agencies on matters that are relatively important for each agency. If such system does not prevail, the agencies concerned will either starve for information or will be guided by misinformation. An information perspective permits a better understanding of the challenges nations face in controlling national security relationships. It may be surprising that even in a democratic system, there may not be effective networking between departments, if the country is not particular about its informational security system. It leads to the statement that one hand does not know what the other is doing. It is more serious when one hand misinterprets what the other is doing. The absence of professionally managed information networking in a country will lead to rumours and information leak, information blockade and starvation. It will also be an ideal scenario for interested parties to plant rumours against national interests.

The term “information network” emphasises the path of continuous exchange of information between organisations that are originators and recipients for specific information. Relationship in such networks will be horizontal and informal or formal without a contractual obligation. The obligation is strictly that a department or organisation will have towards national security within the character of a state. Every system in a country should have its path of unhindered information flow in the network: economic systems, market force prediction systems, administrative systems, science and technology (innovations), educational systems, internal and external security systems, diplomatic geostrategic systems, political systems, etc. Government is one of the many actors in this chain. New relationships will always open up in information flow. It is also applicable for information that flows across borders. Correct information flow in the international network upgrades the geostrategic attributes of a country.

Information networking will be technology oriented with advancement in all fields of communication. Technological improvements are critical for effective informational security management within a country and across its borders. The role of the government is in linking local networks with broader systems in such a way the information flow is unhindered and does not permit leak, rumours or starvation. Information flow networks should be integrated with national technology policy for this purpose.

17.8 Informational Security in Military Strategy and Information Warfare

Military strategy of a nation depends heavily on information. Information security is correlated with technology. The command and control systems (C²) graduate to communication, computers and intelligence (C⁴I) with the introduction of informational security within the military aspects of security management. The C⁴I is designed around information-related technologies. Informational security management in military strategy is quite challenging with respect to mobilising, fielding, protecting and enhancing the force in a military situation. In a general statement, it can be said that informational security developments should run concurrently between military strategy and other national requirements. It could be networked effectively within the national system. To that extent, information technology is a critical technology for informational security.

Convergence of informational security in military affairs leads to netcentric strategy. Those who were in a better position for information warfare always had the strategic and tactical advantage in military affairs over their opponents. A nation that does not have an effective informational security network running concurrently with military strategy and other national requirements cannot achieve a higher degree of effectiveness in information warfare. It is a myth that information warfare can work in isolation without an effective informational security mechanism in place in the non-military information aspects. Military strategists often overlook this requirement. It is similar to any other national activity and its correlation to military affairs that leads to revolution in military affairs. A stable and technologically advanced industrial structure, national infrastructure, food and logistics back up, scientific and technological background, etc. are very much essential for national power and military security. National informational security prospects, similarly, will guide the achievements in information warfare.

In information warfare, the aim is to get at the opponent's information stockpile and deny them own information. It may include many activities. While denial, destruction, defacing, exploiting, corrupting, etc. may form the attack mode, protecting own information from the enemy will be in the defensive mode. Information warfare is not complete without exploiting the information available with the enemy even when there is no declared war. One of the advantages of information warfare is the ability to undermine the enemy by exploiting its information without actually having to fight a war. Information warfare is not exclusively reserved for declared wars. It can be waged anytime since the nations are constantly at war, in a sense, at any given time.

Information warfare attacks can be internal or external. They are mostly direct and covert. The attack will be on data, software, hacking into the system, destruction, deception or replication. The data will be attacked by insertion of another to make the original malfunction. Deceptive propaganda and bogus communications are one form, whereas corrupting the data, overloading, jamming radio stations, spamming, exploitation, etc. form the more serious part of data attack. A more subtle attack is

damaging the software. Hacking is unauthorised entry into the system and damaging or corrupting it. Destruction is by physical attacks on the target or support systems. Overloading is possible by attacking the input systems electronically by directed energy sources. Exploitation is extracting information unauthorisedly from the trusted paths. In deception, the target is allowed to continue, but in a manner decided by the attacker. It is also partially exploitation. In disruption or denial of service, the attacker does not destroy the target but puts it out of operation or makes it temporarily unreliable. In information warfare, knowledge management is the key to winning a war, but that alone cannot do it. Military strategists should understand. At the same time, failure of information warfare techniques can cause serious setbacks in actual war. Information warfare does not stop here. A step ahead is the plans afoot in the world to develop psychotronic and psychophysical weapon systems. It will be a new strategic arm unique in information warfare. This apprehension has been made by Russian authors on the subject matter in 2000 quoting American Physical Society for the year 1993.³²

Attacks with such weapons can not only harm the individual psychosomatically but also block the freedom of will at a subliminal level, damage the ability for political, cultural and social self-identification and manipulate societal consciousness that can lead to destruction of collective identity. In other words, the citizens will turn into plain zombies when attacked with psychophysical weapons in an information warfare scenario in the future world. The Russian view is that such weapons are already there and are being used without formal declaration of war.³³ They called for national and international legislation on norms aimed “at the defence of human psyche against subliminal, destructive and informational manipulations.”³⁴ Such event in information warfare that may turn it to psychotronic warfare is a matter of serious concern among the prospective threat attractors.³⁵

Information warfare is not just war by computers or war with them. It is developing into serious business in military strategy. Netcentric warfare (NCW) is an advanced theme on the effective use of information in winning a war. It needs constant interactions between the military and the industry. Netcentric warfare (NCW) is the integration of two Cs—computers and communication—in the C⁴I leading further to C⁴ISR (command, control communication, computers, intelligence, surveillance and reconnaissance).³⁶ Information is value in warfare. It is not just value addition. The operational effectiveness of the force increases with correct

³²Babacek, M. “Electromagnetic and Informational Weapons: the Remote Manipulation of the Human Brain.” *Aerospace and Marine International*, Vol. 1, Issue No. 16, 22 August 2004, pp. 16–18.

³³Ibid.

³⁴Ibid.

³⁵Ibid.

³⁶The command and control terms and their enhancements are originated from the US Department of Defence. It is not necessary the terms are followed globally by the militaries.

information. NCW is based on the information grid between the public carriers including that of the government and the armed forces.

There was information attributed to China using microwave weapons against Indian troops along the disputed border, which India declared as fake news subsequently.³⁷ But more than fake, transience of the information in social media makes it a weapon of information warfare. Many recipients will never see or hear the corrigendum on fakeness given by India. This is where information turns into a weapon. It is not the microwave or direct energy weapon (DEW) using microwave that is important here but the information about it. It can turn into a weapon. It will cause damage anyway. Governments, therefore, will have to assess the power of information warfare and the damage it can cause to arrive at the countermeasures in the threat to target mode. The ethicality of warfare and covert and subversive information activities need to be examined by the global community to avoid silent killing by deceit.

Deceptive and direct use of information can turn it into a weapon. Frightening and misguiding people using information jeopardise national governance. It is also a matter of falling ethical values and principles that is not appropriate to responsible sapient systems. Information warfare and all kinds of deceptive tactics using information are serious issues in informational security. Information needs to be protected effectively from causing damage in human systems balancing under right to privacy and right to information.

17.9 Protecting Information

Information is highly susceptible to threat. It is a threat attractor in national security governance. Information has to be protected at all times depending upon its vulnerability. In fact, every bit of information is vulnerable. If not handled appropriately, the information tends to become misinformation or incorrect information. Refining knowledge out of corrupted information is difficult and almost impossible. Protection of information is therefore necessary to retain the facts and to disseminate it when necessary to the desired recipient without outflow. Leaked information ends up as rumours or threat accelerators.

Information is protected by specific infrastructure designed for the purpose. Here, the vulnerability of the infrastructure is to be carefully studied and analysed. There are various means or devices designed to guard information against a broad range of

³⁷Times Now Digital. "China's use of 'microwave weapons' declared fake news. But what are directed-energy weapons? <https://www.timesnownews.com/india/article/china-s-use-of-microwave-weapons-declared-fake-news-but-what-are-directed-energy-weapons/683558>. Accessed 18 November 2020. It was said that some reports in the British media, a professor at Beijing Renmin University claimed that Chinese soldiers turned two key hilltops at the border into a "microwave oven," forcing Indian troops to retreat. India's Press Information Bureau (PIB) rubbished these reports and cautioned the public against such reports.

hazards, including crime, fire, accidents, espionage, sabotage, subversion and attack. The security system will depend upon the hazard faced by a particular information. Information may face various hazards: leak, compromise, destruction, counterfeiting, deceptive defacing to misguide, etc. A data, for example, can be accessed and changed without causing suspicion even in a military system. A programme can be uploaded into a system where it may replicate to destroy or change the data. A competitor can gain access to proprietary data. Anything can affect the safety of information: mismanagement, complacency, accident or a hostile deliberate attack or deceptive strategy. It is not applicable to military strategy alone.

There could also be non-proprietary data, which may be treated as innocent. Often, it may not be so. This data could become sensitive when combined with other data already accessed by the opponent. It has become quite easy to access information in today's world. The sensitivity of information is to be seen independently and by combining with other sensitive information in national security matters. Against this backdrop and that of futuristic information warfare, informational security leads to another aspect of the subject: ethics and protecting human mind from remote access.

Protecting information is not keeping them away from those who have the right to know. The right to information makes the governments accountable. It is more so in a democracy. The people have the right to know. This is the Cartesian "I know, so I am" principle. The theories are based on actual understanding of the constitution and legislations on the right to information. Some may say the right to know is the right to live. A human system becomes participative when there is right to information. Just like the way shareholders of a company have access to the balance sheet, the public may have to have access to the government's reports without which freedom of information does not exist. But what kind of information does the government has to provide in such case is a debatable question often addressed by the respective governments and the public grievance committees or similar organisations. In some cases, it is argued that information should be in public interest or it should not affect national security concerns. But individuals can have their own requirement of knowing information. The grievance committee, in cases where the information was not given, can treat it as misadministration. Handling information can also control grapevine and arrest the rumour mills. This is the positive side of sharing information in participative style of governance. The people are made aware. The public knows the governance that suits them, though often they may not get it.

17.10 Information Trafficking

Information trafficking is a deal that is likely to flourish in the knowledge world in the future. Whether it is a criminal act (domestic or transnational) or not, as in the trafficking cases of Crimes3⁺, is a matter of question. But it is a moral crime of privacy violation that could cause injuries to humans and human systems. In case of criminal activity, information trafficking may have to be charged under the law

associated with a suitable act which may not be direct to the act. There is no exclusive information trafficking act. The available acts are based on breach of secrecy and so on. It may not be hideous from the morality arguments when a third party “provides” information about a hiding fugitive to the police. Still, it is in acceptance when the state pays the “informer” a previously promised sum. In the Hollywood westerns, such people were heroes. There are professional fugitive hunters in the world today whose services are requisitioned by government agencies on a consideration. But what happens to a society when the informer is paid by the fugitive or a terrorist to pass information on the movement of law enforcement and other security agencies? Here, the consideration may be money- or fear-induced insecurity. Many terrorist leaders with a bounty on their head survive under this proxy—by reverse information.

Information traffickers were always there in the world from historic days. Today, one of the big challenges for informational security is to protect information from professional information traffickers. They are the people who, sometimes, very well organise, collect and sell information that anyway is not of interest to them except as a saleable commodity with huge profits. They sell information to the concerned party who finds it interesting and critical. It could even be outsourced intelligence. This has given a new dimension to espionage and, thereby, to intelligence. Tourists, adventurers, officials, business employees, diplomats or anybody who is somebody in the know may find a useful buyer for what is known. It could be an underwater profile, magnetic resonance data of the seabed, archaeological finding, government policy document or insensitive documents that may be sensitive in combination with other information, communication, electronic signatures, radar ranges, underwater parameters, acoustics profile, industrial reports, etc. Anything will do. Information traffickers are kinds of bounty hunters in the knowledge domain. Information trafficking is fashionable business with enough legal cleavage today. The business of professional lobbyists thrives on information. The governments have to know it when they give licence to various agencies under new economic and other policies. The governments have to see that information traffickers are not going to have hidden opportunities in anything they do. Information trafficking is done by third parties who generally have nothing to do with the information except it has a value in the information market.

17.11 Psychological Operations and Information

Psychological operation (PSYOPS) is manipulating information to achieve certain objectives. The objectives could be to confound the target community and drag them away from reality to a situation that is favourable to the initiator. Psychological warfare is an activity within the spectrum of information warfare, though it is seen differently from the way it is conducted. In a strict sense, information warfare beyond the realms of computers enters the mental terrain into psychological and, in a more advanced stage, may progress to the previously mentioned psychotronic

warfare. Though partial to the mental terrain of select population, psychological operations and other information warfare tactics have not refused to leave the geographical terrains yet, since they are supplementary to the activities related to the identified elements of national security. That is why information warfare including psychological operations are at the lower end of the spectrum of conflict and can be waged even before a war is fought whether in a declared situation or under proxy. Often, it is silent. Most of the psychological changes take place without being noticed and, inadvertently, by strayed information, cultural shifts and human relations across ethnic boundaries—all within the human mind. Information warfare, to that extent, is at the doorstep of the mental terrain. It may creepily edge into it one day without warning.

Psychological warfare is not a new concept. Sun Tzu has mentioned about it in his treatise *The Art of War*. PSYOPS was practiced by ancient Rome, the Mongols of the Middle Ages and the European Colonial Empires of the nineteenth century.³⁸ PSYOPS was basically the strength of the weak in those days like the way it is today for the militants who depend upon terrorist attacks and threat warnings. Terrorism, in a way, is psychological warfare against a target society by manipulated engendering of disturbing information. It is a psycho terror most of the time. It is a cheap and extremely effective weapon of the weak and criminally engaged. Informational security can contain psycho terror to a considerable extent and thereby has the capability of countering terrorism. Unfortunately, this area lacks attention of the governments all over the world. The efforts of the United Nations in holding a conference on Islamophobia in 2004 could impact terrorism, if followed by effective information management. Information could be channeled towards the fundamentalists and taken up as worldwide programme to make people aware of the phobia. It may contribute in subduing fundamentalism within Islam. There is a need for acceptance of communities by each other rather than dividing, which, from the point of informational security, should, though very gradually, wean away fundamentalism and ethnic violence. It can be studied by biomodeling. Today, those, other than the terrorists, who practise PSYOPS have one specific objective in mind, though not usually practicable: zero casualties among own forces. However, there are questions on ethicality. The media too plays a major role. The reach of the media with its embedded journalists is gradually increasing. People are attentive to the media. It is only a matter of time that media will be there for everyone and could display what is happening in other parts of the world, thereby swaying emotions. Controlled media management of information may call for a different approach compared to what it is today. Media can swing PSYOPS.

PSYOPS have often been talked about as propaganda war that included broadcasts, dropping of pamphlets over the enemy territory, manipulating the media and basically all aspects of information transmission. It will be successful only if the planned activity achieves in bringing modified behaviour in the target audience. It is

³⁸Lord, C. and Barnett, F.R. (eds.). (1989). *Political warfare and psychological operations*. National Defense University Press. p. xii.

a planned use of communications. In the case of hostile groups, PSYOPS is aimed at demoralising, confusing and disorienting their way of thinking and thereby behaviour.

17.12 Mediated Communication and Information

Mediated communication is a term used to refer to communication carried out by the use of communication technology. In mediated communication, data or information are passed through a medium that uses technology appropriate to such communication. In one of the definitions (Marieke de Mooij, 2014), it is any form of communication other than oral, meaning mouth.³⁹ In this study on informational security, mediated communication is about information conveyed through various types of media using technology in governance information systems. To that extent, the term media in mediated communication is the plural form of medium for communication excluding human mouth. It comprises the print media, the audiovisual broadcast media and the electronic media including the Internet. In simple terms and for the purpose of this study, a mediated communication is any form of communication that is not unmediated, where unmediated communication is when a person speaks directly to another. In unmediated communication, the subject matter of communication, the information, directly passes from one person (the sender) to another (the receptor). Any such communication could also be in mediated form; that is when transferred through a medium. The mediated communication is a matter of serious interest in governing informational security. Here, the attention falls on the media and their impact on national security. For this study, all communication need not be information. Information is refined data which is acquired through communication.

That means media carries data, not information. Data contains information that has to be refined or extracted. Media are neither information outlets nor communication outlets for this study. They are data outlets. Data to decisions is a simple flow process. To consider a media as part of information is difficult because it is providing raw data in all cases. The media satisfies various aspects of perceived security in the form of spiritual security. One of them is the movies, the audiovisual posser, correctly said as the opium of the masses since its invention, first in visual form and thereafter with audio added. The receptor in the two-part game of communication comes to the media and extracts what appeals to him or her as information. Often, it may not be the right information. Information if not right will decay by short half-life. Hence, media is not something which national security governance has to see dangerous or alarming. Media not only carries data but also communicates them. Media is more a visible board than a closed chest for storing unrefined or refined information. They are the means of communication to the masses. Media do not carry information. Considering the difference between communication and information, the problem is

³⁹de Mooij, M.(2014). *Human and mediated communication*. Springer. p. 5.

to understand where do the media belong. The receptor to the media has to extract information. Once it is done, the concerned media has served its purpose of communication through delivering data. The data is packed in small little packages like the packets. The data are in various forms in the mediated communication that act as data carrier. The term media is plural; it contains a whole lot of stuff in a whole lot of forms and shapes that contain information that needs to be analysed.

Media is dreaded by some and pampered by some. Few are indifferent. Few cannot manage without daily media access because the absence of data flow can impact perceived security. Media satisfies the urge. Someone important had made a statement years ago that today's newspapers would turn out to be tomorrow's fish wraps. In other words, they are disposable, and therefore, decision-makers may overlook them. This study doesn't agree. One has to be sentient to information in a human system. Newspapers even otherwise end up in the trash cans on the roadside after reading or scrap shops for sale to recyclers. But the information stays with the people. Media will remain media and behave like media. Mass media communication can provide immense gratification of perceived security to many. The fact is that the media, whatever type or nature it may be, handle information-rich data with a purpose to communicate to the universal audience. It is not clear about the audience in a focused manner. It could be anyone, even the fish wrapped in a newspaper and the fly on the telly or computer screen, provided they are alive and could read, watch, hear and appreciate.

The role of the media is a much-discussed term. It has to be established in informational security. The media belongs to the free world and it demands freedom for executing its functions: to inform, educate and entertain. The importance of information management for the media depends upon the role it has assigned to itself among the three. The aspect of informational security lies in its function to inform. Whether it has to preserve the national values or not is in its policy decisions. This is especially where the government has the need to inform people about national matters. The role of the media under such conditions is very obvious—support governance towards national security maximisation because national security is everyone's business. It is for this reason the media is sometimes referred to as the fourth branch of the government (the fourth estate) besides executive, legislative and judiciary in the normal course of checked and balanced governance. It is not because it is not constitutionally stated. But it can act and be treated as one. Media informs people about what is happening around them in their quest for survival. Distortion will affect informational security. This is assuming the government is sensitive to the will of the people.

The media, therefore, is a link between the people and public information besides its value to education, entertainment and all the nitty-gritty's of spiritual security matters. It is reiterated that spiritual security is the extracted perceived security that is added to apparent security for total national security. This is just to understand the overall national security concept. To that extent, the media is not just an instrument of apparent security alone. The media-national security combination is for optimising informational security for NS_{max} . The media can lose its credibility when it turns hostile to information and corrupt it. In this process, the media may

scrutinise the government and its governance. It is more of a people's arm than that of the government in this aspect. The officials are the employees of the people and the government belongs to the people. These equations are clear. Media can do justice to informational security in its idyllic sense with impunity. Freedom of speech is more or less a decree, embedded in the constitution. Only the degree varies depending on the type of governance. The media is the guardian of this freedom. If so, freedom of the press is the freedom of speech that the citizens enjoy. At the same time, it is wrong to conclude that a media has to limit its boundary within the limits of a specific nation. Its responsibility is universal. If that is so, it needs to respect the national governments when data or information is shared with the people. An information that is not considered to be appropriate from the national security point of view to be transmitted to a particular society of people, therefore, has to be withdrawn from transmitting by the information media as not cleared for transmission. This is what the ethics of the media is talked about. But it is simply a question of informational security. Protecting the information is presenting it in its actual clarity provided it can be presented. It is not banning information or looking it up unless that is necessary in the overall national security requirement. For this, the media should function in the appreciated national security centric system, not as an instrument of profit, fame or power outside it.

The media has its obligations within its right to freedom and as the informal fourth wing of a system of governance that accepts it. It is not a constitutional allocation. Media is obliged to discourage abuse of power. Does it mean it is a watchdog? If so, who will watch the media? *Quis custodiet ipsos custodes?*⁴⁰ None? It should watch over itself. It is a glorified position a media holds in a society (Box 17.1).

Box 17.1: Is Media the Watchdog of Governance?

Yes, provided it can watch over itself. And if media rises to that level, then it can watch over global governance of the global human system beyond national boundaries. Simply put, the watchdog factor of a media in national governance will depend upon its watchdog factor in watching itself.

A media can justify its role as a watchdog of governance only if it can watch over itself. The media has high authority under freedom of communication. The media, therefore, should invoke its freedom to ensure informational security in a nation guarding itself from deviation. The media is also subject to scrutiny of the media. The power of the media need not be as formidable as it is projected in many cases. In some sense, the media is highly regulated by various other organs that have been in

⁴⁰“*Quis custodiet ipsos custodes?*” is a Latin phrase referred to the Roman poet Decimus Junius Juvenalis (C. 55–127) in his work on satire genre. It is literally translated as “Who will guard the guards themselves?” though it is also known by variant translations such as “Who watches the watchers?” and “Who will watch the watchmen?”

interplay with the management of information within the national system. Competition and affiliations within the system have taken away most of the power from the media. That leads to the statement that the news gets rotten and forgotten very fast. If the news does not sell, then media itself may be forgotten, unless, of course, the media becomes a habit. Citizens turn the roulette of information through various forms of media. The media have the uncanny knack of habit forming among citizens. It is part of human life.

The main complaint of the media is that governments support them when in favour and oppose when not in favour. There are fact check processes in the governmental system to verify the facts behind the information. But there are chances within the binary axial pressures executed through governments or directly for the authorities of the polar kind to suppress or support the media excessively beyond the two limits. This natural trend on one hand may violate informational security whereas on the other make the individual citizens aware of the deliberate damaging of information that has been one of the causes of distortions in history. News media is not expected to provide news under ignorance. Any violation, therefore, has to be under deliberate intention. This is a lemma that needs to be seen further through hypothesis testing.

The media work under extreme pressure which is also under competition. They spend on advertisement and contribution for survival. Most of the supports come from government revenues for which they may have to please the governments or those who contribute the dole for survival. In other words, informational security through media is always under a cloud of doubt because of the Damocles' sword of survival. Hence, the media tends to move between the axes of binary polarity and settles down in the more comfortable zone at any given time.

Media has self-designed functions. One of them is to separate the grain from the chaff. In this process, media may project the vacillations in the public mindset to governance to the government and the people, with the intention of supporting national security governance. Media is not meant to govern by advising governments what to do as the decision-makers in government are in the right position to appreciate the situation. Media should bring out the flaws of governance and the success analytically to the public. The media opinion cannot be without prejudice for various reasons. But the media can certainly attempt to steer through the prejudice for incorporating checks and balances in governance. Checks and balances are essential in a human system because of the limitations in humans. Prejudicial views on information will balance by information generated by counter prejudice as a mirror image of flawed or corrupted information. This is clearly visible in political discussions. Counter prejudice is inbuilt in informational flaws in governance. The media, irrespective of its nature, have serious roles in information generation and flow in national security governance. This role has to be designed and structured by the media themselves. Hence, all in all, it is a matter of monitoring the media by media which ultimately holds the key to public informational security besides the government and its agencies including government media. Public interference and constitutional measures of correction should be more than sufficient to

keep the balance in a free media. This depends on the freedom a citizen avails in a country.

Media have grown over the years to a mind-boggling strength and variety. They are more than sheer information suppliers. It can accelerate growth and decline. It can induce a feeling of security and at the same time frighten people to the extent that they remain holed up. The media barons become celebrities by themselves and not by rubbing shoulder with celebrities. The media are also no more independent. Most of them are connected with a different activity profile—as the mouthpiece of something or someone. Media can be government based, political or faith system sentiments affiliated, business house related or owned to promote vested interests, etc. Under such circumstances, it is difficult for the employees of the media to rely on the principles of informational security beyond the authorisation of the system they belong to, though there are checks and balances at every step. Forces and counter forces are in interplay with respect to information. Acceptance and denial goes side by side. The citizens have a choice to take or assimilate what they want. In this process, though initially the citizens may be misguided or may misjudge information based on their belief in the media, soon they get enlightened about the information once assimilated within the information system. They will understand the slip of the media in a busy and vibrant world. The problem is that memory is short lived. Soon information bombards the mind. Media in many ways can misinform, especially in the narrow lanes of non-independent individualism. In spite of the problems that it may face, the existence of free media is an indicator of a nation's strength. The freedom enterprise flourishes where the media is free and limited by itself as the guarantor of information. The experience of societies and the plight of free-thinking media personnel in a restricted media environment bear testimony to this fact. Can the media have a body to regulate its activities? Such a body could strangle its freedom and thereby informational security. Restrictions of freedom of the press could be extremely damaging to national security in the long run. A free state does not censor the media. Regulating the media is violation of the constitution in most of the cases. The media has to regulate itself because it is also bound by the constitution and the well-being of the people. The people represent the only body that can regulate the media and that too under the maxim that the media should be free. Ultimately, it is the media that is its own regulatory body in a democratic system. This enlightenment too has to come to the people from the media for a two-way communication related to informational security within a nation.

Media as one of the pillars of national governance is an accepted fact since long. Though not in the constitution, it is an enviable status for a body to be considered that way since it is a tacit understanding and acceptance that media induces checks and balances in a society for its well-being. Media has the power of information, and the issues can make or break the societal fabric. The arguments for the media in information security are the opportunity to reach out to the people and government sincerely, intellectual acuity to express the goings-on, prowess for investigative reporting and authority to maintain checks and balances in governance together with the government. Whereas that against are proneness to controversy, false reporting, hasty reporting, destructive criticism and the image in certain cases that

the media does not generally reflect the voice of the people, but of its opportune possessors.

17.13 Paradoxes in Informational Security

The paradox about paradox (antinomy) is that one has to be clear in appreciating the meaning to identify them in various situations related to knowledge generation, retention, dissemination and regeneration. Paradox is a self-contradictory statement. Paradox related to human interaction appears in communication which is the medium for data and information transfer and delivery. Paradoxes influence information. To that extent, paradox means a seemingly contradictory statement which when probed deeper may be found to be true. There could be many sound and reasonable statements and propositions in communication and information delivery including the truth behind the information itself, but unacceptable or self-contradictory. That is a paradox. Contradiction is a major paradox, but there could be truth behind it. Contradiction may not be acceptable in judgmental situations but is very much up to the standard and meaning in logic and philosophy and in matters that deal with life as a carrier of communication and information passage way. This can be seen in many literatures and discourses on human life system analysis.⁴¹ This study considers contradiction a vehicle in human communication. It may demand specific studies. The position of contradictions in knowledge and communication was mentioned earlier in this book.

Paradoxes in information did not gain much weightage in spite of its early appearances in human communication. If the mention of Noah's Ark in Genesis is about the need to build a boat to sustain life post a flood-induced disaster, the paradox conveys the fact that it has to be done much before the flood rains start and not after. That is the exactness in communication. The critical time⁴² is the factor of paradox. Information systems do not consider paradoxes concealing any specific clues. They are always made or prepared sans embedded paradox. The very fact concealed in the Tower of Babel under the curse of God is a paradox in a storytelling mode. It simply points out to the fact that conveying a message to another is not an easy task in a human system. It doesn't say one should stop work on the tower. But it could make work to stop for one and another that communicates better to sustain. Humans experience paradoxes every day in communication. That is what is highlighted in the paradoxical *Bhagavad Gita*, the wholesome manual for live humans. The scripture relies significantly on contradictions to communicate the truth.

⁴¹ *Bhagavad Gita* the Hindu book on life is actually a kind of user's manual for the self to drive towards self in life (author's explanation). It uses contradiction to explain what is by what is not. There is reality hidden in such expressions. That explanation is paradoxical in one way.

⁴² The critical time for an activity is the most effective time for executing it—not before, not after.

There are barriers to communication. Hence, to convey a message to another, one has to cross the barrier. But is it so with other living systems—monkeys communicating with each other when their territories are breached, plants communicating to another about problems through pheromones,⁴³ phytoplankton under stress in the ocean informing others with bioluminescence (chemiluminescence). . .? Perhaps, the sinuous intellect facilitates humans to surmount the barriers through self-effacing or concealed paradoxes. If so, it could also mean paradox is a creation of human intellect to overcome limitations in matters of information and their dissemination. Often, they fail because of the limitations of human conceptual views. That is why they are self-effacing. Of course, one doesn't know and, therefore, can only deduct and appreciate. Paradox exists in human communication. It is to be accepted. And if it is so, it will impact data and information delivery also. That is till, if this assumption is right, human intellect can handle truth as information. This could also mean what we define a truthful information need not be information if information is to be based on truth as stated earlier. In other words, if information has to be truthful, it needs to dabbled in paradox for an infinite period in human life to make it acceptable information, still imperfect as information.

The literary stream, the main highway for knowledge to intended destinations, has umpteen examples of paradoxes in information communication. One among them is Pinocchio's⁴⁴ paradox in concealment of the truth. In the fictional story, Pinocchio is an animated puppet who was punished every time he tells a lie by elongating his nose. His nose grows. Soon it becomes unmanageable. The Pinocchio paradox was suggested in 2001 by the 11-year-old Veronique Eldridge-Smith, daughter of philosopher and logician Peter Eldridge-Smith who liked the formulation of the paradox and wrote about it in the journal *Analysis*.⁴⁵ The paradox starts when Pinocchio says, "My nose grows now." It is a version of the liar's paradox which is defined in the statement "The sentence is false." That means if it is false, it should be true according to philosophy and logic.

The quality of communication has never been good in humans. It is filled with paradoxes. In the overall outlook while technology of communication is continuously improving, it only provides access and convenience to people but does not improve quality. Perhaps the quality is declining according to some. But the author believes that the quality cannot decline as humans advance in evolution awareness too improves. Hence, the quality of human communication should be improving. But probably the human system is unable to appreciate it under the law of invariance. This happens when the demand on communication increases. This is necessary for governments to understand in informational security. The breakdown of

⁴³ Pheromones emitted from a plant can send out warning signals to other plants in the area of possible infestations by insects that burrow into them for laying egg or cohabitation as parasites. <https://www.google.com/search?client=firefox-b-d&q=howdo+plants+communicate+through+pheromones+with+another>.

⁴⁴ Collodi, C. (1883). *The adventures of Pinocchio*. YouHui Culture Publishing Company. It is a fictional story conveying a paradox and not a fairy tale.

⁴⁵ Journal of philosophy, established in 1933.

communication during election process and associated conflicts anywhere is an example. There has to be only one truth but different candidates that see the truth differently in an election. It even reflects in the elections of the two big electoral democracies of the world—America and India. The communication about the unitary truth collapses totally during elections. If it is about the wanton and unproved complaints about the electronic voting machines (EVM) in India, then it is about the watermarked ballots in America (2020).

If acceptable, it means technological advancement doesn't pave for effectiveness of the activity associated with it. Chris Chittenden in his paper on paradox of communication highlights it.⁴⁶ This doesn't mean technology has to be stopped. There is a paradox here: Can advancement of technology be stopped by a governmental system? Perhaps a virus pandemic may stall it for some time. That's all. Here again there is another paradox. Can a government invite a virus pandemic to stop covertly the advancement of technology to limit the possibility of decline in the quality of communication (or for any other reason)? Well, it goes on like reflections in parallel mirrors facing each other. The information in informational security sways accordingly.

Chittenden states technology opens up accessibility and easier means of conversing with each other in communication, but the medium and act of communicating are vastly different. The crest and trough principle of a wavelet matters here. The crest covers the shallow of the wave. That makes them together by extension. This was also the same in the energy principle of the castle on the beach and moat around it. In information, it means one has to be ready to differentiate the trough from the crest. The captains of ships in the ocean are aware. The governments and their governance that have been compared with ocean sailing should also know it. That is why paradox in information will remain with the intelligent being—the sapiens. It is important to understand it.

Chittenden adds that the problem may lie with the interpretation of communication. The general view is that communication is about passing of information, if reversed information is separate from communication. The application of information may require communication. In the social context, communication generates relationships. It becomes a behavioural aspect. Information is the package that is transferred from one to another by the act of communication. The study of paradoxes applies to both.

Humans communicate with others within a social context. In other words, they communicate with others to take care of their concerns and to build and maintain relationships. Communication is successful when people assess that others take the time to listen and understand what is conveyed and then act accordingly to address the concerns that are communicated. The key to successful communication lies only partly in the medium; it primarily lies in people's ability to effectively use the language of communication. There are moods and emotions in play in the

⁴⁶Chittenden, C. (2000). "The paradox of communication." Talking about. <https://www.talkingabout.com.au/TheParadoxOfCommunication>.

communication domain that can extend to the perimeter of the entire human system, the nation. The element of informational security has to deal with all types of paradoxes at every step, besides difficulties in communicating with another. Information paradox is widely accepted in cosmic sciences and other scientific studies. But its application in national governance is not studied and examined widely.

17.14 So, What Is Informational Security?

Informational security, in this study, is the ninth identified element of national security in the chronological hierarchy of 16 elements. Informational security, “infosec” in short with the symbol “i_s,” is about governing information, including intelligence, for national security maximisation. There is a difference between informational security and information security. The latter, information security, is about ensuring the security of information, whereas informational security is an element of national security optimally governed for maximising national security along with other elements of national security. This difference should be understood in usage and application of information and intelligence.

In governance, information is processed data that have been continually acquired and collated. The data when refined in the process result in information and thereafter intelligence with further refining. Intelligence is when information is upgraded further with the knowledge of intention which is also information. As the national security elements cannot stand alone (one of the qualifying characteristics for an element), informational security too pervades all other elements of national security. The information thus aids the government for decision-making in governance.

Information is the key in decision-making. Therefore, it is vital in national governance.

17.14.1 *Definition: Informational Security*

Against the background of this study, informational security means “*the capability of a nation to identify, acquire and process data for generating and extracting information including information related to intentions as intelligence for decision-making in matters of national security and national security interventions for governance continually as an ongoing progression of governance, perfectly aligned with the other elements of national security and integrated with all the terrains of national governance.*”

17.15 Summation

Informational security as an element of national security is applicable to the geographical and physical terrains currently. Information management is vital for national security efforts that need people participation in every aspect of it. Without people participation, governance cannot perform its tasks towards NS_{max} . Informational security maximisation depends on the success of the government and its agencies in containing the information that are prejudicial to governance and national interest and not withholding information that are required to be known by the people in its correct perspective for ensuring participation. Notwithstanding these two processes, it also matters how information is used by the governments to overcome threats to national security—preventing and containing rumours, establishing effective intelligence machinery, PSYOPS against sources of human threat, regulating information overload, etc.

In a well-governed country, people have freedom of information within acceptable limits. Such freedom helps in governance rather than distorting it. Information is the pathway within the knowledge world. But has the knowledge world ever risen? In the beginning of this chapter, it has been stated that the world has entered the knowledge era. At the end of it, the statement seems to be a bit of an exaggeration. It does not seem to be so. There are people with knowledge; there are nations highly advanced in science and technology; there are also people groping in the dark alleys of ignorance and poverty. They are the majority. They are the world. The entry of the world into the knowledge era will only be when the entire population is knowledgeable and benefited by knowledge. It may take a long time. The process will be extremely slow. The world has not even reached the twilight zone of knowledge-based living. The horizon is still dark.

Information is knowledge. It is the knowledge about everything that supports human well-being. India's *Lok Sabha* (lower house in Parliament) speaker Somnath Chatterjee (2005) views information as a great source of power. He called upon the parliamentarians to be informed for the emergence of an informed democracy. Similarly, an informed electorate can strengthen the edifice of democracy. It is a statement from a much-revered communist leader of India who believes in democratic principles. The right to know and the right to information thus become crucial factors in a successful democratic system. Information should be authentic, objective and non-partisan, hence supporting informed decisions. Democracy is the most preferred and accepted system of governance across the world, and the revolutionary growth in the field of information and communication technologies is the most remarkable developments of the last quarter of the previous century, he stated.⁴⁷

⁴⁷“Information—Great Source of Power.” *The Asian Age*, New Delhi). 21 January 2005. p. 3.

Information refines into knowledge; informational security drives on the path to the knowledge world. And in informational security, “freedom” has an important application—the freedom of information is also the watchdog of informational security. It is not external to the entity that gathers and disseminates information. In national security, each individual has to use the “freedom” to watch over information lest it should adversely impact on it.

Chapter 18

Food Security (Foodsec) (f_s)

Look around; there is food everywhere in a living planet

18.1 Introduction

Thriving life on Earth is the proof that there is food for all to live in its abode. There are statements that humans waste roughly 30% of food produced (2014).¹ Therefore, food security in the sapient world is more about governing food and nutrition for sustainable life. It is about not only the elimination of poverty or hunger but also supporting people's health and vigour. Food is essential to preclude hunger and provide nutrition at the appropriate age in human life. This is what a government has to ensure—access to healthy and nutritious food for all.

Food, the primary essential to sustain life, got entrenched with both grandeur and despair in life—colourful and pompous at one end and miserable and abject at the

¹Food and Agriculture Organisation. <https://www.fao.org/news/story/en/item/262504/icode/%20/>. Accessed 23 September 2019.

other, very early in human existence. Food became a great behaviour transformer. It is associated with carousing glory, lamenting misfortune and establishing social relations of pride, ego and refuge. Devouring food was the main activity in which the emperors of the powerful “middle earths” were engaged between and during the pastimes of perversions—killing, sorcery, witchcraft, sex, orgies and wasting food. Food orgies were symbolic of power, appeasement, provocation, binges of potation and lascivious sexual practices put together. It continues even today; one doesn’t have to be an emperor for that in the present-day world.

Food goes beyond hunger in the sapien world. In fact, feeling hungry without food is still a dark and gritty privation of many people globally. But food means more; it is not a kind of hunger buster alone. Food is associated with birth, life, death and all the intermediaries—ceremonies, marriage, belief systems, faith and conversion of faith, victory, trauma, moral degeneracy, lascivious dissipation, happiness, boredom and above all gluttony of the affluent and powerful and, of course, pictures of starvation and poverty. It shows food binge supports perceived security in a big measure and the governments can satisfy certain urges of the people to find comfort in perceived security just by providing food. People serve food to the poor, busy, uncared for, caught in the executive or activity nexus, under palliative care, victims of disasters. . . . They invoke perceived security by meeting the apparent security needs of fellow humans.

Limitations of gluttony of the rich and powerful extend beyond the girths of their gas chambers in the stomachs and guts. After ingesting to the rim, short of nostrils, they vomit stuffing their fingers in their throats and self-applying siphoned enema to evacuate from the bottom—only to chew again on the putrid carcasses. Sometimes, one wonders how carcasses can be called food by skin-sweating humans that have no canines or short designer intestines meant for flesh gourmets. The living things with canines ate them fresh, not as cooked cadavers from the deep freezer. Maybe the secret is heat treatment of flesh to convert it to a digestible veggie. That means fire, perhaps, changed humans into a species that was not meant to be a flesh gourmet initially. But the food chain gives a different perspective. Humans should eat anything, whether standing or moving, in the food pyramid. The invention of fire, therefore, was not only inevitable but also the first step in human survival mode before transforming from nomadic hunter-gatherers to the next levels of domestication of plants and animals. Fire made carcass compatible with human molars and intestines to bear and belch. Yes, there are differences in the anatomy and physiology of humans and other living things. The most frequent activity—constant, continuous and *de rigueur*—that every affluent and powerful society engaged in was eat, vomit, belch and fart; the more regular they did it, the faster they came down the slope to fall into the grave by sheer gravity. Gluttony, overindulgence in food including drinking, is one of the seven deadly sins according to Pope Gregory I (540–604) who was influenced by writings of the Evagrius Ponticus (345–399). All these add to the mysterious relationship between food and foodies in the game of life.

Starvation and malnutrition (also called hidden hunger), on the other hand, make people forget the purpose for which they are born—to gobble food in every form. Well, that is what the world has seemingly made humans believe. Since there is nothing to eat, those who starve may eat anything till that becomes a coping

behaviour. Toxic seeds, leaves of anything that grows, mud, clay, stones, insects, rodents, creepy crawlies and anything that flies (except aeroplanes and similar varieties). Such coping behaviour keeps lives lingering for a set of people oblivious of the ways of the world, and the powerful national and international organisations and aid agencies are constantly on the hunt for food for the impoverished. Often, they find food faster than they can deliver to those who need it. If they locate them, they may have to explain the difference between the food and the cello wrap that holds it. The starving and undernourished in the world are so downtrodden and emaciated that they may not know whether to eat the banana with the peel or not unless the food faddists give them the owner's manual on eating a banana. There are worlds out there where people have not seen the food the rest of the world eats. This statement is an expression in duality—applicable both ways. The fact is that there are millions who do not have access to food and nutrition in the civilised modern-day world that has enough and more to feed them all.

Oeconomicus (nearly meaning the economist) is one of the works of the ancient Greek historian and philosopher Xenophon (431BC–354BC).² It is a Socratic dialogue principally about household management and farming. It is an early work on economics in its original sense of household management and a significant source for the social and intellectual history of Classical Athens. The author finds it as one of the many ancient biomodels that can be amplified for a nation, the largest human system for the present, in food security and overall governance. For many, it is a military thesis because Xenophon is said to have delved seriously in military matters. The other side of the treatise is that it falls in the self-help book of the ancient kind that contains advices without much merit or experimentation but for thinking in between of what and how. The critics also say Socrates was never a good householder and certainly is not the right medium to choose from. So what is it about? The author's contention is that it was a pupil's way of paying tribute (Xenophon was the student of Socrates) to his teacher and also highlighting the problems of the people—household management, getting the meals on a daily basis at home which obviously has to come from the wife, at least in those days. The replica for food security in a country for the homemaker is the government. The advantage of such biomodels is that it may trigger the how to think nerves of the brain which even the author of the works would not have thought about in those times. Simply put, Oeconomicus can make one think about the production of food and the role the government has to play (like the lady of the house) in farming (production) and serving (distribution) towards food security.

²Xenophon. "Oeconomicus, on the management of a farm and household." Trans. Watson, J.S. *Xenophon's Minor Works*. Henry G. Bohn, 1857. http://bingweb.binghamton.edu/~clas382a/study_guides/xenophon_oecconomicus.htm. Accessed 23 May 2020.

18.2 Food Security: Setting

In the game of word association, food security normally reminds one various stories of starvation and hunger, not affluence and food orgies. Hunger and malnutrition are the two maladies that people suffer in many parts of the world. Food security is, therefore, a challenge to any government including the affluent. Hunger kills nearly five million children every year according to a study by the United Nations in 2004.³ Hunger prevails the world over even after about two decades. Zero hunger is the second goal of the sustainable development goals (SDG) of the UN Agenda 2030. One of the causes for this plateau may be the increase in demographic density that counters the food security efforts of the governments. In early 2020, more than 821 million people are hungry in the world according to one report.⁴ That means one in nine people. In addition, there are millions suffering from malnutrition in spite of getting food and under the risk of famine.

Hunger and malnutrition are the problems of every nation in relation to food security. Only the quantum number and statistics vary. Hunger is the feeling that a person gets when the body needs food, whereas malnutrition is the deficiency of nutrients that a person needs to grow and remain healthy in the food that one gets to eat. A person who remains hungry and who overeats could be malnourished.

A majority of the world's hungry are women and girls. It is a curious case that throws out many hints. It shows the psyche of the world (not just men) with respect to women and children, for one. It has to be seen against the element of ethnic security also where, this study believes, ethnicity is the human-induced and strongly perceived difference between two humans. Women and children are ethnically considered lesser mortals than their male counterparts by the system with hardcore gender bias. Malnutrition means growing up weak and famished. Malnutrition is a condition of individual health. Undernourishment results from a diet in which one or more nutrients are either not enough or are too much such that the diet causes health problems. It may involve calories, protein, carbohydrates, fat, vitamins or minerals. It is the result of an imbalanced diet. The result will be generations that are sick and tired.

Food security, as an element of national security, has to look beyond subsistent life. For this, it is closely associated with health security. That is why it is not a problem of the poor alone. It covers the entire world population from nourishment point of view. It is always believed that developed nations are free from food insecurity, and it affects only developing and underdeveloped nations. Appreciating the need for food security under this belief system will change the outlook totally. That is the reason it has to be seen from the point of view of nutrition-related food security. A general appreciation on the subject will first point out to the need for food

³“Hunger Kills Nearly 5 Million Children Every Year: Report.” PTI News Scan, New Delhi. 9 December 2004.

⁴“The facts: What you need to know about global hunger.” <https://www.mercycorps.org/blog/quick-facts-global-hunger>. Accessed 23 May 2020.

and, thereafter, for nutritional food. Food security, therefore, is a challenge to the planners engaged in keeping the people healthy.

Food security is not about controlling or eliminating starvation but keeping the people healthy by providing nutritional food. Food security is highly interactive with the element of health security. Poverty is an indication of malnutrition in the country. Increase in income also does not normally indicate that people are healthy. In some parts of the economic world, the term nutrition security is applied separately. Often, it is different from food security. But it may be applied under food security as part of it, because as an element of national security, food security cannot be seen as a stand-alone starvation buster. It amounts to regulating food for nutrition and preventing ill health. Nutritional well-being of the people is very much the objective of food security. Preventing hunger is entrenched in it. It is stated in the constitutions of many countries. The Article 47 of the Constitution of India states, “Raising the level of nutrition, standard of living and improvement of public health are the primary duties of the State.”⁵ Combating malnutrition is different from combating hunger.⁶ That is why in food security, concentrating on starvation abolition alone is not the right approach. It will not serve the purpose.

18.3 Food: Basic Need

According to the UN Food and Agriculture Organisation (FAO), a set of people in the world experiences “extreme hunger.” They are the people whose intake of calories is far below the minimum necessary for survival leading to death by malnutrition and starvation. Many people die from starvation. Malnutrition, according to the FAO, refers to the inadequate intake of calories, proteins or nutrients. It is difficult to identify malnutrition as it is more or less silent and appears near the tipping point of human subsistence. Malnutrition sooner or later appears as a health issue and thereby shifts to health security aspects of governance. People suffering from malnutrition are susceptible to life-threatening illnesses and stunted physical and mental development. Malnutrition becomes hereditary, for the children of malnourished mothers.

Nutritious food, therefore, becomes a basic human need. It provides energy for subsistence of a living thing as one of the basic needs. Air, water and food are the essentials of life. Poverty and food shortage are interlinked. Food comes from agriculture, domesticated animals and natural harvesting of food resources—both animals and plants, wherever they grow in nature. Another variety of food is “what one can eat” and may not be involved in these titles. These are hunger-suppressing coping food choices. That could even be dirt. Most of the people who suffer from

⁵ Article 47 of the Constitution of India states it is the “Duty of the State to raise the level of nutrition and the standard of living and to improve public health.”

⁶ Rao, G.M.S. “Food for Thought.” *The Hindu, Magazine*, Coimbatore. 12 September 2004. p. 4.

food and nutrition deficiency in the world are located in South Asia and sub-Saharan Africa.⁷ It is a generalist appreciation, though.

Sufficiency in food means more than just farming. The capability requirement is for research, technology, regulatory measures, food processing, water management, fertiliser management, trade, transportation, distribution and other infrastructure for sufficiency in the food system of a country. This will need heavy investment and political support in public development. The measures taken should emphasise the competitive production and distribution of food products and access to the market in a country within and out of it in the international market across trade barriers in a competitive scenario. The commitments have to be coherent, realistic and effective.

Everybody needs food. Therefore, food security is a concern of all governments. “From where will the next meal come?” is a subconscious question for many. The World Development Report 1986 defines food security as “access to all people at all times to enough food for an active, healthy life.” The FAO (1983) defines it as “ensuring that all people at all times have both physical and economic access to the basic food they need.” Another definition (Staatz 1990) is that food security is “the ability to assure, on a long term basis, that the food system provides the total population access to a timely, reliable and nutritionally adequate supply of food.”⁸

According to Rome Declaration on world food security, poverty is a major cause of food insecurity and sustainable progress in poverty eradication is critical to improve access to food.⁹ More than 800 million people in the world, particularly in developing countries, do not have access to sufficient food to meet their basic nutritional needs (2001). The cause is not shortage of food but the lack of access to it. Supply and distribution constraints, continuing inadequacy of household incomes to purchase food, instability of supply and demand and natural and human-induced disasters contribute to it. According to the FAO, the problems of food insecurity in its global dimensions are likely to persist and even increase dramatically in some regions.¹⁰

The key areas in food security are agriculture (including livestock), division of labour, environment, forestry, nutrition, fisheries, rural economics, population, education and communication. It is not an issue related to developing or underdeveloped nations alone. Hunger can remain even in a strong economy. In the United States, nearly 20% of all children live in food-insecure or deformed households.¹¹ About 5% of the children lived in households where at least one individual experienced

¹¹OS (name withheld) was one such child—a Nigerian-American whom, years back, the author tutored geography, social studies and maths as a voluntary tutor in a school in Washington, D.C., USA (1993–1994). His parents could not offer him much because of various handicaps (withheld). The kid (innocently) desired to become a (drug) “pusher” when he grew up, but at the end of the year during a farewell lunch at the Smithsonian cafeteria, he confided that he wanted to become a

hunger. The general trend of food insecurity is on the increase, according to a survey.¹² Some 40,000 people die every day worldwide from hunger-related causes according to Ismail Serageldin, chairman of the Consultative Group on International Agricultural Research and vice president of Special Programmes of the World Bank.¹³ According to Serageldin, the surplus demand for food has to come from increased biological yields and agricultural transformation through genetic research. Factors that affect food security are many. Among them, the economists evaluated the state of affairs by taking into consideration the following factors relating to food grain production in India:¹⁴

- (a) Public capital investment in the agricultural sector
- (b) Per capita daily availability
- (c) Financial health of the economy
- (d) Result of the anti-poverty programmes: partial crossing of the poverty line, non-generating assets and low recovery rate of loans

These factors, though applicable to India, can be useful to any other countries with certain variations in assessing the situation at a particular time and the trend that will follow thereafter.

18.3.1 *Right to Food*

With food being the basic need, every human has a right to it. Governments and those governing human systems cannot disregard the need for food for humans. The right to food, and its variations, is a human right protecting the right for people to feed themselves in dignity, implying that sufficient food is available, that people have the means to access it and that it adequately meets the individual's dietary needs. The right to adequate food cannot be underplayed by any government. The right to food and the fundamental right to be free from hunger are very much recognised by the international law. The right is protected under international human rights and humanitarian law. The corresponding obligations of the state are well established under the international law. Article 25 of the Universal Declaration of Human Rights (UDHR) and Article 11 of the International Covenant on Economic Social and Cultural Rights (ICESCR) recognise the right to food.¹⁵ Many

cop (like you, he said to the author). That was a turn in personality. The author doesn't know where he is today (2020) but wishes he is a cop trailing down the (drug) pushers.

countries have endorsed them in their constitutions. Article 22 of the Constitution of United States is specific on the right to food. It states, “the State recognizes the right of every citizen to decent housing, education, food and social security.”

The right to food is a human, legal and clearly defined right which gives rise to obligations of states to reduce both chronic undernourishment and malnutrition. As a human right, it provides the right to all humans to live in dignity, free from hunger, food insecurity and malnutrition. Dignity is the key word here. Protecting it is the role of the government. In the legal context, the right to food entitles a person the right to claim it. Under legality, national governments are under three types of obligations: availability, adequacy and accessibility of food to its people. It is a simple domestic chore of a concerned homemaker in a family who ensures nutritional food for other members.

18.3.2 Governing Right to Food

Governing food security, therefore, is about ensuring food for all to satisfy hunger (achieve zero hunger) and provide nutrition for good health and well-being.¹⁶ It is a task the national and international governments should ideally ensure. The underlying principle is to understand that food security is not about suppression of hunger alone but also providing nutrition for peoples’ health and well-being. According to the FAO, there are two types of hungers—extreme hunger and hidden hunger (Box 18.1). Both can impact health security seriously. Malnutrition, hidden hunger, affects the brain cells and general health. People have the right to live. That is why the right to food is human and legal and thereby an obligation for the governments to exercise and account for.

Box 18.1: Extreme Hunger and Hidden Hunger

According to the FAO, extreme hunger is chronic undernourishment causing starvation and hidden hunger is malnutrition. According to the FAO, many people die of extreme hunger daily as their intake of calories is less than what is necessary for survival. Hidden hunger is when there is deficit in the intake of calories, proteins or nutrients. A person may receive high calories but still suffer from nutrition deficiency.

Voluntary Guidelines to support the progressive realization of the right to adequate food in the context of national food security (Right to Food Guidelines), 2004, and [Voluntary Guidelines on the Responsible Governance of Tenure of Land, Fisheries and Forests in the Context of National Food Security](#), 2012.

¹⁶Sustainable development goals 2 and 3, respectively.

Governing one's right to food is the prime part of governing food security by the governments. Every government should take serious initiatives to ensure regular supply and distribution of food ensuring it reaches the people. In this effort, the governments have to ensure all aspects of land holding, irrigation, farming, agriculture, storage, pricing and distribution. The focus is on access to healthy food for all. Once food is made available, the government will have to ensure acceptability and healthy utilisation. Climatological changes can impact farming and distribution seriously. Farmers count on seasonal rainfall which can betray the food producers. Infrastructure limitations can impact on food distribution especially the types of food that are fast perishable. People in inaccessible terrains face the risk of food shortage. Another challenge is farmers shifting their jobs. This will be evident from the rural exodus to cities which could result in double jeopardy. On one hand, the farming sector will be affected, and on the other, the townships will be choked with people who are unemployed leading to social issues. Though it is not easy to handle human migration or people's inclination towards job, governments can certainly hold people in the desired jobs by making them attractive through human investment management. Governments will need socio-cultural developmental activities to retain people in their career holds by balancing distribution. This is a challenge for countries irrespective of their demographic densities. It means each country may have to identify and adopt country- and location-specific plans for food security.

Corruption and other abusive social practices can topple the plans and interventions of any government. This is quite common in food security governance in countries where the political system is lethargic and abusive practices are predominant. It requires sufficient laws and law enforcement to establish and ensure the rule of law in matters related to food security. The Government of India follows a national food security mission centrally launched in 2007. The aim of the mission is to increase production of essential food commodities, ensuring farming sector welfare for productivity and economic enhancement. There are various other policy decisions associated with food security. It is a huge population that countries like China and India have to feed nutritionally.

18.4 Food Insecurity: Curse of the Affluent World

Food insecurity is historically linked with population. It is admissible even today in spite of technological advancement. But in a real sense, the world was not starving for food except in pockets where food never reached or among people who could not find the means for a meal. The Malthusian¹⁷ theory of population increase and corresponding agricultural land depletion still hold fort. In a world with 6.5 billion people, about 12.5% suffer from poverty and thereby the lack of access to proper

¹⁷Thomas Robert Malthus (1766–1834), the British economist in 1798, propagated the theory in economics.

food. The World Food Summits organised by the FAO during various periods in the past reaffirmed its objective of reducing the number of hungry people. The problem is correlating the reduction with the population increase by the target year. Even otherwise, the FAO cannot be sure about achieving the goal unless the political will of national decision-makers and the energy of civil society and bilateral and multi-lateral resources are mobilised effectively. It is an objective that is vague ab initio. But there is hope in the FAO as an international organisation considering food security maximisation is better achieved with global partnership rather than the world powers taking advantage of food crisis through aids and food supply with an eye on geostrategic domination.

There is a difference between the lack of food and the lack of access to food. In the global perspective, there is more food than required for everybody, but it may not be available at the desired location within a nation. The problems are complex even for a developed nation especially when it means distribution of nutritionally rich food. The good news is that food is available in plenty in the world. The scarcity is because of failures in the distribution system. Governments have to mainly pursue a good distribution system for food security in a pragmatic manner. It doesn't happen all the time. While food rots in one corner, starvation deaths are common in another part. Starvation is different from poverty. It is worse. Poverty may still yield food, but starvation at its best may induce "coping mechanism."¹⁸

The lives of many people, from birth to death, are ruled by a coping behaviour in food habits. They never taste the real food in their lives. Even animals have a fairly good chance of getting what they want to eat. The stories from various parts of the world especially from Africa, the cradle of human life and the world's richest region for resources, is too poignant to narrate. Sudan is still reeling under the twenty-first century's first genocide that reminds the conditions of humans in the period of Black Death and incessant wars for vainglorious reasons. Over 100,000 Sudanese who fled as refugees face extreme starvation in Africa (2004). They eat up everything around their refugee camps. Prominent was mukhet berries that have to be soaked for days to remove toxins. They are dried and ground up to make flour that has virtually little nutritive value. Far away from Sudan, in Haiti's slums, there are portions of dough dried in the sun with ingredients such as butter, salt, water and dirt. This is an irony of fate in a world where the rich desists from eating rich foods and the United Nations declares obesity as a global threat. In many places in the world, there are millions starving for calories and proteins. In Malawi, children sell skewers of roasted mice on the roadside. In Mozambique, grasshoppers may eat crops and the people eat grasshoppers; they call them flying shrimps. In Ghana, there are people who fight with ants to collect the tiny grains they carry in spite of the fact that some of them cause havoc in their allergic systems. In Liberia, during the civil war in 1989, almost all animals in the zoo vanished. Dogs and cats disappeared from the streets. In Kuito, Angola, in early 1990, a family survived a few more days by

¹⁸ McNeil Jr., D.G. "When Food is Not an Option, Leather Soup, Dirt Biscuits and Bugs will Do." *The New York Times Articles Selected for Asian Age*, New Delhi. 2 June 2004. pp.1-2.

drinking leather soup from furniture leather after removing the tanning chemicals by soaking in water for a long time. But the victims of the Soviet famine of 1930 have eaten furniture itself. In Eritrea, women strap flat stones to their stomachs to lessen pangs of hunger. In the starving world, there are mothers who boil stones to cheat their children by making them believe the food is almost ready. They wait for the children to fall asleep in the meantime.¹⁹ The lullaby of hunger resonates in the boiling stones. In Zambia, balls of edible clay are sold in markets. In Angola, black dirt called “black salt” is sprinkled on cold food. The dirt biscuits of Haiti are called *argile* meaning clay or *terre* meaning earth. *Argile* is a staple food, like the mice in Malawi, of the very poor. Making them has been a regular business for years in starving Haiti. And all over the world, these coping foods are available in one form or another aimed at the poor. They are strictly not foods but coping meals that control the hunger pangs of the food converts.²⁰ How long the world and its governments can be indifferent? It is said that in a controlled environment, people can starve for about 40 days. But famine is not a controlled environment. People could die early.

As mentioned earlier, food insecurity is not caused by lack of food but poor management and control of available food and food-related toxic effects on human health. Since 1500, food historians argue that no famine was caused by lack of food.²¹ In many cases, some political force stops food from arriving. Examples are: British indifference during Irish potato famine, Maoist crushing of peasants in the Great Leap Forward in China, clan warfare closing ports in Somalia,²² onions vanishing from the markets during one of the election propaganda periods in Maharashtra, India, etc.

Food security policy is aimed at alleviating hunger and improving nourishment to the people of the world. According to the findings, in the last decade of the twentieth century, a large chunk of population in developing countries has been freed from hunger under the FAO programmes. At the same time, there are countries that have recorded increase in the number of people who are not free from hunger.²³ During this decade, there were 843 million undernourished people in the world—798 million in developing countries, 34 million in the countries in transition and 11 million in developed countries. In October 2003, 38 countries were reported to be facing serious food shortages requiring urgent assistance: 23 in Africa, eight in Asia, five in Latin America and two in Europe.²⁴

A large part of the world's population that lives in stomach-grinding poverty is mostly rural. This is a result of increased disparity of distribution of income and food. Hunger and malnutrition are the key enemies of food security. In a world well endowed for food production, resolving issues related to food insecurity is relatively simple if there is political will and determination supported by good governance, even though it involves interacting with a complex array of factors. Many of them are variables. Population growth and distribution, environmental changes, economic and political systems, ethics and belief systems, climate change, trade barriers, land availability, research and development, science and technology, legislative measures and a host of other factors are involved. The world food problem indicators can be misinterpreted if the standard food requirement per individual is taken as that consumed normally by people of a developed country. They are privileged to have better and more food than the average in the food-insecure countries. Food standards and the nature of it, besides the calorific value, can vary from region to region and country to country for optimum food security. Each country has to have the standard staple diet details for food security maximisation. The policies should be based on the determined standard of food as well as the expected quality of life under food security. The quality of life under an effective national security regime will be still further up. Food security maximisation is a step towards upgradation of the quality of life of the people.

Poor and poverty-stricken people are those who are incapable of growing or buying food for their subsistence. Hence, it is an issue that may figure in most of the elements of national security. Poverty prevails in large parts of the world. The hot spots are many. For this reason, the solutions for resolving food insecurity had been thought out much earlier and were seriously considered by governments. However, most of the poverty alleviation plans failed. Some of them were partially successful. This explains the reason why they vanished in the course of time and new organisations and schemes came up spearheaded by the FAO under the United Nations. Some of the previous plans promoted by the developed world are listed in Table 18.1. This does not include the FAO promotions.

The Marshall Plan was proposed by George C. Marshall (1880–1959) while he was the US secretary of state in 1947–1949. The plan was designed to develop the economies of 17 western and southern European nations by alleviating poverty and other social problems to prevent people getting influenced by emerging communist policies. It was more an ideologically motivated attempt that included food security as one of the identified objectives. In fact, in all such plans (Table 18.1), the common factors were direct and indirect involvement of the United States as an emerging superpower and the objective of containing the expansion of communism and communist ideology in a world that was reeling under poverty and unemployment subsequent to the world wars and prevailing economic insecurity. The situation was ripe for the people to be attracted by communist ideologies, another form of social structure where, to sum up in a nutshell, the communist party owns the state that owns the nation and its people. The state is expected to provide primarily the basic physical needs to its people. The ideology strictly revolves around food, employment and, to a certain extent, health in a system that is limited without choice. The plans of the west, however, provided food for the poor in many parts of the world in spite of the existent agenda behind it. There was always volunteerism, philanthropism and other projects that served in a limited manner in feeding the poor. Today, the world has collected under the United Nations; alleviating hunger and malnutrition of the world remains a distant dream, though.

There is no definite way to decide poverty and food insecurity. It is a relative expression. From the socio-psychological standpoint, poverty should be based on the inability to satisfy the primary needs in a human being. To that extent, a human who cannot buy food is poor. The rest is relativism with respect to governance in food security. To overcome difficulty in choosing the poverty paradigm, the governments, depending upon the country and other parameters, devise special measures like social security, food coupons or a measurable line like the poverty line as the standard for subsistence food allowance. Being below the identified poverty line makes one eligible to be considered as poor and get the benefits from the government on a natural scale that may vary from time to time.

It is an irony of sorts that among those who suffer from food insecurity are the agricultural and similar food-producing workers in most parts of the world. That includes traditional and other small-time marine and freshwater fishers also. Compared to them, other industrial workers and labourers are better off. Uneven distribution or lack of food is the basis of food insecurity in a nation, society and even within a family. It is an interesting find. It shows the interplay of belief systems in a society or smaller formal groups like a family. In a book authored by a once successful businessperson, it has been mentioned how his poor parents struggled to bring him up as a child who at the age of seven was the only earning member of a very poor family. Every night, he returned home late. He sold newspapers on the street. His mother would be waiting to feed him with the meagre food she could cook for the day. The rest of the family, especially the mother and sisters, would partially starve saving their food for him, the only earning member of the family. Tough there are many in the world who live like this but not fortunate to become an industrial

tycoon like him, the story talks about it all²⁵—how societies and families distribute available food under certain belief systems and vagaries of life. The physical needs of a person cannot be considered under restrictions. Some of the food-sharing methods in a poor family may be argued as very pragmatic. Such families and groups are highly exploited in a society that has no scruples. Landlords, religious institutions, communal organisations, criminal syndicates, etc. thrive on food insecurity by providing food to the poor and slowly getting them into their mould. Food is an object of attraction. This causes collateral damages in a society. The intricacies of food insecurity are not only hidden in the physical health of the society but also in the way it affects ethnicity, demography and the social system.

This brings out the reasons how developed nations too suffer from food insecurity. The cause is government apathy. There is hunger, poverty and malnutrition in developed and affluent nations too. The reasons are not shortage of food but the lack of access to it for some. In food security, the reasons and solutions will be country specific. That is one of the reasons why the intentional poverty alleviation programmes in the past could not make much headway in their food security objectives. Such plans will have a common approach to the problem and that need not be exclusive to a specific country or people. There are many preferences and belief systems associated with food and its management. It is also wrong to believe that food insecurity will be resolved when people earn more. More earnings mean more consumption. That also means the more poverty in eating segments, the more expensive the food commodity for them. Food insecurity is not to be misconstrued for food crisis. Food crisis is food insecurity in a crisis situation. Managing food crisis is different and has to be worked out by food aid workers and volunteers in areas affected by food crisis. Often, the crisis is due to other factors rather than food insecurity. For example, there could be food crisis on a railway accident site in a remote area. A flash flood can cut away food supply and damage local reserves causing food crisis in a locality or region.

A food-insecure nation also becomes vulnerable to geostrategic exploitation very seriously. The psychology of food aid is very much questioned in a world when an aid supply is aimed at gaining a foothold or keeping a rival at bay from interfering. Food insecurity, therefore, is a serious geostrategic threat attractor. An aid with strings attached can cause more damage than it can undo. Take an example. The country “A,” a peasant society, is suffering from serious food shortage due to an unexpected drought. Problems are severe. The politicians are feeling the heat though they eat well. The reserves of food in the country are low. Country “B,” the affluent and geostrategically smart operator, was always looking for an opportunity to get in. It promises huge food supply free of cost and the authorities and decision-makers are comfortable because their interests are also taken care of in the corruption route that already exists. The smart donor country “B” purchases extra food from its farmers who otherwise would have burnt them to hold the price line by reducing the

²⁵ He went into bankruptcy and then became a fugitive for economic offences much later in his life which is another story, though.

supply level. The farmers and other food producers in country “B” become richer and develop a feel for the government for the extra dole. The food stock, thus purchased from the farmers, is kept aside by country “B” holding distribution to country “A.” The old trick (not known to be practised now) was in delaying the supply. Already the country “A” and its leadership are under obligation to the good donour supporter who came to their help at the time of need. The public, especially its supporters, in country “A” is chanting praise in the name of the donour. But the food stock will reach very slowly. The donour will ship them in a calculated manner in their own ship bottoms and through their own distribution channels, at each stage taking advantage of the offer. The delay may be crucial at the other end. But the people under the promise and the reserve food already on its way within their own country cope with it (like the children who fall asleep when their mothers cook stones in front of their sleepy eyes). When the aid reaches the market in country “A,” the season would have changed. The next crop of indigenous food supply is ready to hit the market. Now there is a surplus. Prices will crash and a select lot in the country will make it rich. Farmers will suffer in the new season too. It ends in a double jeopardy for country “A” that sought the aid from an unscrupulous geostrategic manipulator. Though everyone in the aid route is richer and stronger, it is the peasants at the end of the line in country “A” that undergo double jeopardy—first by nature and second by their own government’s apathy, wrong strategy and poor governance. But the world is aware of it now and hardly there is any more such food supply directly between country to country except in cases where there is genuine and situation-based understanding. Besides, the United Nations, through its programmes, regulates the mode of supply in a starving world.

18.5 Food Insecurity and Coping Behaviour

Food insecurity is often associated with suicide and other individual and group behaviour patterns especially in peasant societies. But more than that, it could be a major cause for riots. Some such riots are even termed as food riots. Food insecurity is a facilitating condition for violence that is rationalised by those involved in it. The French Revolution (1789–1799) that led to the peoples’ rule bred from the lack of bread among others. Such justification makes people feel certain amount of impunity. The feeling that how someone can punish a starving person for a violation guides the people through the extremes in response. An extension of this feeling can be seen in the violence associated with fishing rights and harvest skirmishes, etc. Naxalism in India is one such old behavioural philosophy that has come out from the agricultural fields. Naxalite movement started in India when the poor but hard-line farmers took arms against the landlords under the influence of communist ideology that lingers on in different shapes. Naxalism in its original form in India came as a political ideology, not strictly based on poverty and food insecurity. It was the outcome of the split in the Communist Party of India in 1964. The breakaway party was known as the Communist Party of India (Marxist) [CPI (M)]. The new

group wanted to free the land from the landlords who were holding large part of lands under the zamindari²⁶ system. In spite of the abolishment of the zamindari system, large holdings of land by single parties and exploitation of the poor farmers continued. It was when a restless part of the CPI (M) indulged in armed struggle to free such holdings of land for distribution among the exploited farmers. The ideological diversion of a branch of communism exploited the situation of poverty and the decadent social status of the poor farmers working under the control of the rich landlords. The hardliners of communism gained strength and formed the movement of the Communist Party of India (Marxist-Leninist) in 1969. Soon the armed peasants forcefully took control of farmlands in Naxalbari, in West Bengal, India, from the local landlords. It soon spread around. But in the course of time, the movement disintegrated under mutual distrust, ideological differences and firm-handed state incursion. Parts of the movement exist in select areas of rural India, still capable of causing serious disruption to the state governments by parallel governance. Such insurgencies can also provide sanctuary to vested interests of individuals and groups. Economic reforms and consumerism besides socio-political engagements can decline such parallel movements.²⁷ However, there are views expressed elsewhere that naxalism is not yet over since they cleverly use the ceasefire and other parleying situations to strengthen themselves.²⁸ It is a socio-economical problem turning into a fiery political one. Food security maximisation is one of the stretches along the route to manage the issue.

Food riots have also become a thing of the past. There were serious food riots in the eighteenth- and nineteenth-century Western Europe that are popular among historians engaged in the study of human violence. They found a correlation between food prices and food riots. The mute form of disobedient behaviour today where food is an instrument is the hunger strike, actually a leading refusal to work propagated by Gandhi during his non-violent movement against the colonial British. It is still followed in India and other parts of the world by people who desist the acts of the more powerful—often the government. The underlying psychology is violence associated with food insecurity. Non-violence is violence packaged in a different form. According to author Donald L. Horowitz, food riots come from the feeling of “moral economy.”²⁹ Not all food riots are part of it. Throwing of tea in the

²⁶Where a landlord (*zamindar*) owns large part of the farmland and peasants cultivate agricultural products as labourers on payment of meagre wages and remain poor at the same time. Naxalites and communists consider this as exploitation of the poor.

²⁷Banerjee, S. The Naxalbari Movement, The Fire that was, www.bengalonthenet.com. 1 December 2004.

²⁸Gupta, R. “Since Naxals won’t Bid Farewell to Arms.” *The Asian Age*, New Delhi. 3 November 2004, p. 13, and Mustafa, S. and Parsa, V. “Naxals Use Clout with Parties to Build Base.” *Asian Age*, New Delhi. 14 February 2005. p. 1. According to the second article, the problems are acute. Many of the Indian states harbour Naxalites in their fold. All these units are serious.

²⁹Horowitz, D.L. (2002). *The deadly ethnic riot*. Oxford University Press. 2002. p. 327.

famous “Boston Tea Party”³⁰ is associated with food though not connected with moral economy but nationalism. It was reported that the food riots continued in many parts of Germany even after prices were stabilised. That rules out the moral economy as the favoured reason and shows food scarcity could ignite violence and other patterns of vehement behaviour in a restless community.³¹

A government can lose election if food is pricey. The electorate can turn anti-government. There is a credibility deficit for the government in such situations. It is a good playground for the opposition to pin the government. Though declining as the world is very much improved now, food riots or riots associated with food³² as the basic underlying cause is expected to continue. There are many economic determinants in a riot other than food that needs to be mentioned to avoid ambiguity. Stealing the rich to feed the poor is a food-induced activity practiced by the legendary Robin Hood and many similar country heroes around the world. Unlike other forms of riots, food riots are not seriously destructive.³³ They are aimed at stealing concessions or establishing rights in traditionally established terrain whether land or sea, associated with food security.

18.6 Food Production: Trends and Perspectives

Food production is highly vulnerable to environmental degradation. There are concerns that food production in the world is slowing down by environmental damage and other reasons. On the other hand, there is also news that food production is increasing. Such variations show deficiency in analytical appreciation of a situation. Food production is resource based. It absorbs multiple resources such as land, soil, fertilisers, water, plant, animal and energy resources. Resource use also contributes to environmental pollution. Fertiliser is one such pollutant. It is stated that by urbanisation and industrialisation, the cropland area is declining in some parts of the world. There was a mention of localised urban conglomerations within a rural region to prevent internal migration of people, especially peasants, in the chapter on demographic security. This proposal, besides not being capable of holding people within its objective, also suffers from the drawback of reducing the cropland area within a country. All these factors need to be taken into account when the issues of food production are discussed. Though the food production in the world is

³⁰ On 16 December 1773, American patriotic nationalists disguised as Mohawk Indians threw away 342 tea chests overboard from a ship that docked in Boston Harbour as a protest against British colonialism. The tea belonged to the British East India Company. They were protesting against tax on tea as well as the British monopoly over it.

³¹ Horowitz, D.L. (2002). *The deadly ethnic riot*. Oxford University Press. 2002. p. 327.

³² Riots associated with food can be those related to farmers, farm products, restrictions in food laws, distribution, free doling of food and so on.

³³ Ibid, p. 425.

impressive compared to the past, population increase is causing the demand to exceed supply. This brings decline in per capita food production.

World food production is encouraging. Global cereal production for 2003–2004 is evaluated at 1874 million tonnes.³⁴ Cereals are the base diet of people. The base diet always should be available in reserve stock supported by effective distribution system. Cereals can be preserved in bulk reserve stocks without difficulty. Inadequacy in food production increases dependency on reserve stock. The agricultural commodity prices are an index of food security. The higher the prices, the higher the insecurity on a demand and supply scale. However, it has to be viewed country specific. The livestock production in the world was of 249.1 million tonnes of meat and 599.1 million tonnes of dairy products in 2003. It continues to grow significantly faster than agriculture as a whole and accounts for 45.2% of the total agricultural GDP according to the FAO assessment. World trade in fish and fish products has increased (2003) by 8% since 1998. Forest products also made significant contribution to international trade. However, the FAO feels there is much to be done to balance the trade. The director general of the FAO feels multilateral negotiations are indispensable for achieving fairer solutions.³⁵ Population increase will seriously affect food supply. Projected by 2025, 8.5 billion people will require as much food as has been produced since agriculture began 10,000 years ago.³⁶ Population growth affects food supply that in turn can cause ill health. Unhealthy population will invite allied problems.

Tragedy lurks in the lives of many families that subsist on their employment on farm fields. It is visible if the attention is shifted from the world of plenty to the dark alleys of peasants' homes of not so affluent nations. When there is silence, one can hear a whine of agony from the unlit rooms of poor farmers in certain states in India. It reverberates over the whole village like a chorus of the dead. The cry emanates from the families of the poor farmers who committed suicide under the burden of debts and harassment from moneylenders.³⁷ Some of these stats are quite affluent

³⁷ "British Policies Blamed for Farmers Suicide in Andhra," *Hindustan Times*, New Delhi. 17 May 2005, p. 6. According to the report, a study had claimed that trade reforms, backed and funded by the British Government, had caused an agricultural crisis in India, sparking suicides by impoverished farmers. The study as reported was by Christian Aid, a charity. In this reform, farmers were encouraged to take loan and produce cash crops for export at the expense of staple crops like rice and wheat. The farmers were unable to repay the loans owing to fluctuating global prices. They were then forced to approach unscrupulous moneylenders. Between 1999 and 2004, over 4,000 farmers committed suicide. The agencies blamed in the report had denied the link between suicide and market reforms and argued that the reforms helped around two million people.

through technology revolution. It is unbelievable that there is a section of society who cannot find their next meal. In the first half of 2004, about 2000–3000 farmers in the state of then Andhra Pradesh reportedly ended their lives under mounting debt burden that accumulated by parching heat waves over their croplands.³⁸ The spate of suicides became a political issue that resulted in the routing of a government in an election (2004) in spite of its much touted flagging the information technology revolution. Bill Gates, the then chairman of Microsoft, one of the world's leading information technology companies, had paid a visit to the state. He showered praises on the government for its bold executive decisions and determination. But the people had a different view. They changed the government. Even when the new government took office that promised relief to the farmers, another 100 killed themselves out of sheer debt and frustration.³⁹ This may have an answer rooted in human survival psychology but, under a common belief, is attributed to poverty. Prima facie the cause is attributed to parched land and crushing debts that shrink self-esteem. The debts are to banks and moneylenders. Compound interests to the loans and harassment by nasty recovery agents compounded the tragedy. The debts are marks of shame for a farmer. The lenders exploit the shame to psychologically torture the farmer and his family to get the money back with heavy interest. Death comes by swallowing pesticides. They are available in plenty since the farms have gone dry. For some observers, death is not directly attributable to poverty, but honour. The ignominy associated with auctioning of their land was stated to be unbearable to the farmers. The issues are as hot as their desiccated land holdings. Solutions are not forthcoming to end this problem. Situation becomes worse when interested parties fan the fire.

There are also myths associated with food production. One such myth that has been reported in the media is about the direct impact of the monsoon on food production. While on one hand India is considered to be a monsoon economy,⁴⁰ a study showed that food grain production doesn't depend only on rainfall according to figures.⁴¹ It states that agriculture is not strictly a gamble on monsoon and rainfall. The pattern of rainfall has an influence over farm production, though. In India, the experience shows some interesting variations. This is given in Table 18.2 showing the monsoon rainfall against food grain output from 1987 through 2002.⁴²

It can be seen from the table that there was about 19% depletion of monsoon in 1987 and 2002. But the food production rates varied. In 1987, production was 140 million tonnes. Production increased by 31% to 184 million tonnes in 2002. The 2 years when compared 15 years later could have the factors of advancement of farm technology and other calculation errors. The bottom line is that in most of the

2000	92	196
2001	98	212
2002	81	184

^aPaleri, P. (2008). *National security: imperatives and challenges*. Tata McGraw-Hill Publishing Company Ltd. p. 303

countries, agriculture is a high-risk-prone economic activity. It needs resilience. The table shows lack of direct correlation between monsoon and agriculture production. Monsoon precipitation was 100% in 1993 and 1995 based on the long-term average of 88 cms. But food grain production, which was 184 million tonnes in 1993, dropped by four million tonnes in 1995.⁴³

There are counter arguments also. In 2019–2020, the food production got a boost with excess monsoon. Those years had the best monsoon in 25 years.⁴⁴

One of the questions that a country has to ask itself is the desired mode of food production. Is it self-sufficiency in food production or sufficiency in export of a certain commodity and import of another? It is a big question though most of the nationalistic aspects propounded the former argument in the past. But with global control of human activities, it is quite likely that the world may prefer trading products to producing all, especially when there are far too many limitations in achieving self-sufficiency than trading commodities around in a global security environment. Only very few countries have achieved the status of serious food exporters in the world. The United States, Canada, Australia, Argentina, Western

Europe, New Zealand and Thailand are the world's more successful food exporters (2004).⁴⁵

Food is not produced from agricultural lands alone. Marine fisheries and other marine biota (seaweeds, etc.) that are used as food and nutritional intakes are major sources of income for an entirely different section of the society—the fishers and the sea farmers. Their lives too are linked with the vagaries of existence experienced by the agricultural farmers. The difference is in terrain. Overfishing and marine environmental degradation have caused most of the fishing grounds to go dry. While the demand for fish is increasing, the supply chain gets interrupted when the catch is low. Similar to the case of farm workers, it is the ordinary fisher who gets affected. Many traditional fishers in the world live in poverty. Fish farming, especially shrimp farming in various parts of the globe, has done serious damage to the ecosystems than what is gained in food products. The damage to the ecosystem further affects food production. Large mangrove grounds have been cleared for shrimp farming. This adversely affects the ecosystems and the coastline. It is visible in the Philippines where shrimp farming has virtually destroyed mangrove forests.

The FAO has been assisting fisheries administrations worldwide to control the issues of managing fisheries. The growing concern of most of the countries is their inability to manage fisheries in their Exclusive Economic Zone (EEZ). According to the UN Convention on the Law of the Sea (UNCLOS) that came in force in 1984, coastal states have certain obligations regarding their fisheries resources in their EEZ. These obligations are:

- (a) Assessment of fish stocks
- (b) Allocation of surplus stocks to national needs to third parties
- (c) Conservation of fisheries and fisheries habitats

Articles 61, 62, 73, 192 and 194 of the UNCLOS are specific to living resources at sea that deal with conservation of living resources, their utilisation, enforcement of related laws and regulations, protection and preservation of the marine environment and preventing, reducing and controlling pollution of the marine environment and international cooperation on a global or regional basis, respectively. What is important here is allocation of surplus stocks to national needs to third parties. It is an obligation that is unheard of in land farming. Under Article 62, the coastal state, which is fortunate to have the sea across, will assess its capacity to harvest the living resources of the EEZ. If the coastal state falls short of capacity to harvest the entire allowable catch, it is required to provide access to the surplus of the allowable catch to other states. Here, Article 69 and 70 are also applicable. It is to be done through agreements and other arrangements under the international law. Many countries in the world are alert on the subject of fisheries and are bent on developing and establishing policies and strategies to meet their obligations under the UNCLOS. Other articles that are relevant to living resources exploitation are 63 (Stocks occurring within the EEZ of two or more coastal states or both within the EEZ and

⁴⁵ Anjeneyulu, Y. (2004). *Introduction to environmental science*. BS Publications. p. 118.

in an area beyond and adjacent to it), 64 (Highly migratory species), 65 (Marine mammals), 66 (Anadromous stocks), 67 (Catadromous species), 86 (Applications), 116 (Right to fish on the high seas), 117 (Duty of states to adopt with respect to their national measures for the conservation of the living resources of the high seas), 118 (Cooperation of states in the conservation and management of living resources), 119 (Conservation of the living resources of the high seas), 120 (Marine mammals; it refers to Article 65 here) and 197 (Cooperation on a global or regional basis).

Based on the outcome of the International Conference on Responsible Fishing in Cancun, Mexico, in 1992, the FAO prepared a Code of Conduct for Responsible Fisheries (FISHCODE). There are specific guidelines for the implementation of FISHCODE. The FAO advocates precautionary approach to reduce the risk of damage to the marine environment and living aquatic resources and advises to take the best scientific guidance and take decisions under minimised uncertainty, errors and risk.

18.7 Combating Food Insecurity

Challenges to food security are region specific. The common issues are poverty reduction, especially among the vulnerable and marginalised groups. The government has to reach out to the poorest of the poor and provide them with opportunities. Dialogue with communities and self-help groups is part of this activity. Providing microfinance and technology will supplement their efforts. Strengthening roads and providing appropriate educational facilities will improve productivity. Food security can be met by green revolution that extends from soil characteristics to value addition. This could make up for fall in arable land.

Conflicts, terrorism, corruption, and environmental degradation also contribute significantly to food insecurity. Food security calls for sustainable management of natural resources, elimination of unsustainable patterns of consumption and production and early stabilisation of population. There is also a need for gender equality. In spite of the fact that women contribute substantially to food security in rural areas, they have been subjected to inequality in nutritional intake. In theory, food insecurity can be either chronic or transitory.⁴⁶ Chronic food insecurity is persistent food inadequacy caused by the inability of people to acquire food that is needed for their subsistence. It is rooted in poverty. Transitory food insecurity is a temporary drop in food availability. The factors could be availability, income or certain crisis situation like war. In reality, both the situations may come up together. It is quite fragile and complicated. While managing food insecurity, it is to be clearly understood in definite terms whether it is a chronic or transitory issue. The solutions may vary. The solution for a transitory issue may be incompatible with a chronic issue. Incompatibilities of identified solutions with the problems may prove expensive. In

⁴⁶ Jha, M.M. (2003). *Food security, dynamics and dimensions*, Northern Book Centre. p. 7.

the chapter on economic security, a reference has been made to the attempts of the Government of the State of Andhra Pradesh, India, to send select farmers to Kenya on ownership farming of a leased land. It may be an internal outsourcing of sorts for Kenya and for the Government of Andhra Pradesh finding a way to alleviate poverty of its farmers who are suffering from the vagaries of weather. The question here is whether the solution is compatible with the problem, whatever the problem may be. If not, the future will be at stake at a heavy cost for the people. This book does not examine the issue.

Efforts to combat food security should consider limitations in food production. The ecological limits are more serious because they are irreversible in the short term. There are signs that certain parts of the world may experience it soon. The rate of increase in yield today is much lower. Increased input of water, fertilisers and pesticides does not seem to be yielding at a higher rate of growth. Better strains and genomic approach may be a solution but are experimental and shrouded in controversies related to ethical aspects. Coupled with it is also human health concerns related to food production and security. Animal diseases like foot-and-mouth disease, swine fever, Rift Valley fever, bird flu, etc. have caused enough alarm in health security.

Combating food insecurity may be specific to a country or a region. It could also be at a global level. The correct mix of traditional and industrialised methods could allow containing ecological limitations as well as damages to biodiversity. The answer for sustainable agriculture may lie in many activities: controlling water use, growing perennial crops, minimising soil erosion, preventing salination and water logging, controlling flood and drought, preparing for flash floods, using organic fertilisers, resorting to biological pest control rather than using chemicals, government support to sustainable farming, economic approach to reduce poverty, use of available land resources judiciously, community-endorsed farming, high-yielding plant use, controlling demographic shifts that may cause food problems, etc. The solutions are far too many. What is important is their compatibility to limit the cause of food insecurity.

Integration of farmers and people in the food market will improve agro-ecological consideration and awareness among people. Food should not be an elite act of placing order and being served, but an integral part of human behaviour for sustenance and removing hunger and improving health by nutritional intakes. It is perhaps the only item that is common in everyone's dialogue in a day.

Respecting and complying with intellectual property rights are one of the areas in global food ethics. Though such a move will be seen by many as restrictive, it has the possibility to encourage original research. In the long term, such research will yield better food status by allowing for constant improvement of human intellect. Intellectually modified food products will compensate for other setbacks and limitations. As in industrial production, technology is also the bedrock for farm improvement. Research in the areas of agricultural genetics, biotech, space, radioisotopes, etc. are some of the revolutionary areas for improving food production. The development of post-harvest technologies and food processing will supplement production and preservation process. The technologies in food security are not complicated, though

the fields of these technologies may be. The ideal way is to combine technology with traditional methods.

There are many models of development that the world has witnessed in the past. The success story of all these models can be assessed from the progress the world has made. Analysts may differ on each of these models. The fact remains that there is rampant food insecurity in the world today. It was worse in the past. If that is an indication, and comparing with the past, it is evident that food insecurity can be eliminated, if at all possible, on a very gradual scale that will call for national and international cooperation, development plans based on food security and sheer determination on the part of governments and people. It is not possible since there will be many conflicts in the future in a world that is yet to be stabilised. Within this uncertainty, it is for the countries experimenting with maximisation of national security to underscore the problems of food security as an element that may influence their objectives.

A large country with high population growth needs huge reserves for food security.⁴⁷ Reserves will be required to meet the lean period so that the country does not have to depend upon external sources of aid. Coupled with reserve stock, a good distribution system will support the efforts. Often, this is where the system fails. There is no difference of opinion in the world that, ultimately, it is poverty that decides it all—malnutrition, hunger, health and all other abject situations that a society may face. Poverty is close to food insecurity. The gap between the people in relation to food security is widening continuously. The haves and the have-nots are distinct classes of their own.

There are arguments that only genetically modified (GM) food will reduce the gap between food production and the growing population. There is also concern over their safety that may outweigh their benefits.⁴⁸ It can be seen from the crop burnings in India, protest against the WTO and World Bank meetings and plunging share prices of biotech firms in the West.⁴⁹ The Government of India believes that GM foods have the potential to help overcome the problem of food shortages and malnutrition in developing countries. However, it is essential to ensure safety to health and environment.⁵⁰ Biotech food calls for an extensive research. The norms of research will need careful evaluation and constant attention of governments.

Irrespective of industrialisation, agricultural economy remains the backbone of global economy. It is not specific to a few countries alone. Food security is everybody's concern. The subliminal suggestion in the psyche of food security is, quite obviously, to strengthen food production as a resourceful and forceful sector in all aspects. If a country is a monsoon economy, which ideally should not be that way, the vagaries of monsoon should not be the limiting the criteria for food production

⁴⁷ Ibid, p. 17.

⁴⁸ Ibid.

⁴⁹ Ibid.

⁵⁰ Ghosh, P.K. Genetically Modified Crops and India, *New India Digest*. November–December, 2000, p. 16.

for a determined community. The rains have to be harvested scientifically for irrigation and creating lakes, rivers and reservoirs. Tapping the mountain flow is also a pattern of water harvesting. Another method is glacier harvest. A glacier once harvested will rebuild itself for another. Scientific studies can lead towards these points. Instead, certain quarters advocate linking of rivers. The problem here is that linking of rivers does not produce additional water. It only amounts to distribution or rather sharing it for irrigation and other purposes that may cause unexpected consequences to the ecological balance and environmental stability.

Agriculture is also soil productivity. Degrading of farmlands by salinity and other factors is a matter of concern. The normal method used by people to counter degradation by infertility of the soil is to reclaim wastelands. It is not an ideal solution. An indicator of agricultural decline can be seen in the value addition of a farm worker when compared to an industrial worker. The alarms should ring if it is relatively less. Modernisation of agriculture is the solution. And most of the countries in the world require such modernisation. The problems in agricultural productivity also come from fragmented land holdings.

Research and development in food security is essential to develop high-yielding seeds that are pest- and drought-resistant and acclimatised for the particular farmlands. The impact of economic security in agricultural economy means purchasing power. In a peasant economy, it also means rural purchasing power. But it is interesting to note a find by Professor Ashutosh Varshney of Notre Dame University that in democratic countries, poverty line is higher and showed slower decline, whereas Amartya Sen's findings show that democracy had, without exception, abolished famine.⁵¹ Sen attributes the reasons to the direct methods adopted by democracies: subsidies, job reservations, transfer of assets to the poor, etc. (through land reforms and cheap loan schemes). The indirect route is often an unnoticed passage to permanent economic security: accelerating GDP growth, increasing productivity, market-friendly policies and investment in health and education. This also implies that economic security can be jeopardised by military overinvestment and direct poverty-alleviating methods. Table 18.3 below gives the poverty line status of some of the countries that are governed consistently.⁵² The status is for the early 1990s.

More than the type of government, it is dedication by governance in abolishing food insecurity and poverty in coordination with the global plans that may yield better results in a country in a world comparatively free from economic disorders of the past. The world economy has changed for the better. But economic development does not guarantee food for all. Managing food insecurity involves many factors rather than just a system of government aimed at economic development alone. Research on the subject may ponder many of them:

Venezuela	23

^aPaleri. P. (2008). *National security; imperatives and challenges*. Tata-McGraw-Hill Publishing Company Limited. p. 306

- (a) **Ecological considerations.** Biodiversity and ecosystems are closely related to food production. Managing matters related to them will provide protection to plant and animal resources over the land and water including the seas. There is a need to preserve forests by combating forest fires, safeguarding quality of water and analysing the effects of using biotechnology and genetic modification. There is a large requirement of legislative, commercial, technological, scientific, informative and educational measures in this activity that has to be visualised at a macro level.
- (b) **Agricultural production.** Improving agricultural production by increased investments with a view to wealth generation in the rural sector is essential. It is also necessary to find alternate sources of income in certain sectors of society involved in farming to meet the income requirement for the lean days. In the case of marine fisheries, there are seasons when the fishers will not have source of employment. This is especially so during heavy weather conditions and when seasonal ban on fishing is in force.
- (c) **Weaker systems and habitats.** Identifying vulnerable groups and indigenous people who need special care under food security schemes and developing organisations to meet their interests and improving their habitats and living conditions are another areas for attention.
- (d) **Water resources.** Management of water resources for agriculture and other farming requirements to increase productivity will include water harvesting, control of irrigation and drainage works, rehabilitating large irrigation schemes, restoring rivers and canals, distributing water through irrigation canals and monitoring trends to warn the community against drought and other disasters that may affect food production. Water management techniques for developing desalination and wastewater recycling and water purification are other areas.
- (e) **Trade barriers.** Managing trade barriers with international cooperation is a geostrategic concept that impacts on food security.
- (f) **Quality assurance.** Assuring food quality and safety and consumer protection will require for appropriate legislative and enforcement measures.
- (g) **Health.** Health conditions of agricultural workers will impact food production in peasant societies. Most of them may have limited access to health products

and practices. The health of the agricultural workers is affected in many parts of the world by serious diseases. The agricultural dimension of such illnesses has to be studied for implementing effective remedial measures.

- (h) **Food-related disorders.** Managing food-related disorders is a key issue in food security maximisation. Food security is not just the absence of food but also preventing the toxic aspects of food. Obesity, diabetes, cardiovascular diseases, certain types of cancer and other yet to be identified physical ailments can be associated with food. Such diseases by abundance of “bad” food coexist with malnutrition in the same society.
- (i) **Sustainable development of agricultural areas.** Agricultural areas include rural areas. Their development and preventing arable land getting converted for other purposes or getting damaged by pollution making them unfit for cultivation are part of food security management. A conducive agricultural and rural development programme will keep the food security under sustainable conditions.
- (j) **Conditions of the poor.**
The asset base of the poor has to be strengthened to provide them with the capability to maintain sustainable development of agriculture with the development programmes. This means providing them facilities and resources besides assistance in distribution.
- (k) **Food distribution.** Distribution system that can reach the farthest and the needy at the right time is very essential in food security. Often, food does not reach the needy. Failure in distribution is a major cause of food insecurity in many countries.
- (l) **Surplus and reserves in food stock.** Effective surplus stock for reserves is a must to tide over an emergent situation induced by war and disasters.
- (m) **Marketing support.**
Marketing the product of the poor ensuring the best price is a task that could actually improve the purchasing capability and asset accumulation for better production by underprivileged section of the society to undertake the system.
- (n) **Wage structure.** Finding provision for decent wages for farm workers is necessary to improve their standards and increase their yield for work. Value chain should move both in farm products and agro-industries. The farmers should produce for their needs and market demands. This is achieved by providing technology, credit and better infrastructure for distribution.
- (o) **Support subsidies.** Subsidies, direct and indirect, will help mostly large farmers. The system should serve small farmers. It is important to see that the benefits should not be for those who are already in the upper strata unless meant for competition in the world market with collateral benefits for economic security.
- (p) **Technology.** Technological development and access to it are important for productivity. At the higher end of it is genetic modification. Genetically

modified food, according to the WHO, is not harmful to human consumption.⁵³

A large part of the world already is consuming such foods. The stigma could be removed by careful research and information transparency.

- (q) **Infrastructure.** Agricultural infrastructure for transportation, power, water and ancillaries is part of the development in food security management. Though such infrastructure may require heavy investment, the returns are challenging.
- (r) **Approach principles.** One of the principles of management in food security is to strengthen from bottom up. Normally, the method followed by governments is to start from the poverty line downwards. This process has many inherent shortfalls. It is presumed that everyone under the poverty line is equally handicapped. It is not so. There is a hierarchy down there where the people are still divided. Besides, the people just above and close to the poverty line are also more or less equally unfortunate—like the people across a disputed border. They are not considered while sweeping below the poverty line. That will make them weaker than the line just below them under care in the course of time. So while the line just below the poverty line is uplifted, the one just above slips down keeping the line more or less at the same level. This mathematics of distribution of food is one of the reasons why, in general, the poverty line does not move down in spite of the efforts by the governments. Of course, the reasons are not as simple as explained here. There are other parameters too. To overcome these difficulties, the more suitable method is to start from the bottom of the strata and move upwards clearing up the system en route. This eliminates the concept of poverty line that currently serves only as a convenient datum but does not stress the actual need to eliminate hunger and malnutrition. Figure 18.1 gives different approach paths forweeping poverty as hypothetical examples.

These two methods are hypothetical. The government could experiment the sweep across further to identify the best approach path after preparing a suitable model of the poverty area—the area between the poverty line and the bottom line. It could be different for each country for optimum results. The FAO may find the approach plan in the sweep area from a global perspective incorporating the national models for poverty sweep. The preferred method is bottom up sweep (shown as sweep up method in the figure). It has many advantages; one of them is that it fits all. In sweep down method, the poverty line is pushed downwards till it is eliminated. In the sweep up method, the poverty line is virtually dispersed—not pushed upwards. There is a certain degree of social upliftment here, which is a method to eliminate most of the social problems and not food security alone. To a certain degree, the method advocates attending to the worst first. Though it is noted a new concept, the reluctance in appreciating and practising it in any social situation is that it calls for a cutting-edge efficiency in governance. The other two methods are easy to adapt where poverty sweep is done at random as convenient. Though easy to apply, it will not show results for a long period since the poverty line remains undisturbed even

though certain pockets may have improved within. It is a convenient method in dedicated governance.

18.8 So, What Is Food Security?

Food security, in this study, is the tenth identified element of national security in the chronological hierarchy of 16 elements. Food security, “foodsec” in short with the symbol “f_s,” is about managing and governing food production, acquisition, storage and distribution for all the people as necessary ensuring nutritional aspects from the point of health and health security under the maxims that include the following:

- Food security is a critical need of humans for healthy life.
- Food security is not a mere right to food.

18.8.1 Definition: Food Security

Against the background of this study, food security means “*the capability of a nation to ensure its people at all times equitable and equal physical, social and economic access to sufficient, safe and nutritious food according to their dietary needs, food habits and food preferences, for leading an active physical and mental life, by maximising national security, perfectly aligned with the other elements of national security and integrated with all the terrains of national governance.*”

18.9 Summation

Food security is the tenth element of national security in this study. It is the duty of the government to ensure that the entire population has access to healthy and nutritious food without interruption. For this purpose, the government will have to make certain the production and distribution of food under various methods as it deems fit. There are many tasks involved in this process. It will include production, food-related reforms and research, price control, protection and economic assistance to food producers, elimination of famine, care for food resources below water, continuity of food flow, ensuring employment and trade opportunities related to food production and distribution to people, ensuring action against marginalisation of people in food accessibility and so on. Food is not just a matter of physical need in the civilised world. It is also the philosophical recipe of harmony and traditional identity in human society. To that extent, it is also a psychological need and closely connected with spiritual security. Food security is not only about preventing hunger but also taking care of the nutritional aspects of the population and preventing abuse of food that may affect health security. Fortunately, the world today is comparatively free from hunger. There is enough food, and food production is not threatened globally. There are measures available to contain food insecurity by governance. Food insecurity can occur due to two reasons: (1) food not available and (2) food available but not accessible due to either distribution failure, lack of purchasing power or non-availability of land to grow and produce own food.

But all is not well in the world in spite of abundance of food and knowledge related to it. According to India’s National Family Health Survey 1998–1999, about half of the country’s children are chronically undernourished and adult women are anaemic.⁵⁴ There are allegations that the government keeps food away from the poor and spends more than 100 million Indian rupees a year for “food subsidy.” Only a small proportion benefits the poor. Much of it represents the cost of procurement, handling and storage. Buffer stock limit is about 17 million tonnes.⁵⁵ According to

⁵⁴Sha, S. et. al. from Delhi School of Economics, Letters to editor, *The Times of India*, New Delhi. 4 April 2001, p. 12.

⁵⁵Ibid.

reports, the Government of India has launched a 60 billion rupees programme for rural road development and an ambitious programme for ensuring food security involving an annual subsidy of 230 million rupees in December 2000.⁵⁶ Twenty years later, in 2020, the government had brought out new farm bills and regulations to streamline the farm sector. Though there are political opposition on selective arguments which is natural in any responsible governmental systems, the government is hopeful of consensus among all concerned on matters of food production. It will also help in meeting the goals and targets of the Agenda 2030.

At the global level, the immediate challenge for the FAO and its members is to find the means to reduce hunger and to ensure the basic human right to food. The global governments need to act decisively and promptly to this end, if all national and international stakeholders are to work together in a concerted effort, in the framework of an international alliance against hunger. 16th February is declared as World Food Day by the WHO. Does it matter? Perhaps, if celebrated in empty stomach by all that day to understand the pangs of hunger.

Investment opportunities are required in agricultural and food processing and distribution sectors. Private–public partnerships, rarely experimented along with financial cooperatives and endeavours for modernising and marketing agro-products and agro-industries, are needed. One of the fine examples in the rural world is the Anand experiment in the state of Gujarat, India, in dairy cooperatives and development that made India a classic country in milk and dairy production. The same principles can apply in fragmented farmland utilisation and food product marketing and distribution. Rational access to finance is also important. There is a general feeling that employment can solve not only food security of the individual but also the employee's dependent family. Often, political dialogues make promises of employment. Employment actually provides identity to an individual in the human system rather than just food security, though it is the primary need of a human being. It is the identity that matters for a human being in a society, and a job just gives that. According to a study conducted by the ILO, a large number of employed are also below the poverty line. But the situation is improving globally in its own pace. According to the ILO, generating more and better jobs must become the central plank of the global drive to reduce poverty.⁵⁷ Employment should be job generative.

To sum up, the three specifics—farm, forest and ocean—are the key areas for food generation. Thereafter, it is distribution to the needy. These specifics may extend to a spectrum of logics in food security:

- Optimum arable land
- Optimum water farming area
- Rain and mountain water run-off harvesting
- Optimum forest cultivation area (In certain parts forest food resources come under the term, hill products.)

⁵⁶Vajpayee Launches Rs 6,000-Crore Rural Roads Project, *The Times of India*, Mumbai. 12 December 2000, p. 1.

⁵⁷“Even Employed Live in Poverty.” Says ILO, *The Hindu*, Chennai. 10 December 2004, p. 9.

- Corporate involvement
- Direct sourcing with farmers (This means avoidance of middle people.)
- Food research
- Food production information
- Containing domestic consumption abuse
- Attractive export markets
- Diverse climate zones for variety throughout the year
- Increase in rural income, economy and purchasing parity
- Food processing industries
- Demand for processed food
- Food preservation industries and facilities
- Food distribution facilities
- Optimum reserve stocks
- Government spending in rural-based infrastructure
- Tax incentives for food production and export
- Freshwater and ocean farming
- Fisheries protection, preservation and economic exploitations

Chapter 19

Health Security (Healthsec) (h_s)

Life, in all probability, is a migrant; health, indubitably native

19.1 Introduction

Life was in wait at the entry points till the forces engaged in creation perfected the design of “wholesome” death, that is, when clinically diagnosed as “irreversibly gone” leaving the body behind like an abandoned surgical mask. Death was always a mystery to humans. It is a sentient matter. To that extent it can be said that “if there is anything that beats the spectacle of life, it is the hidden mystery of death”. It doesn’t have to be. But humans prefer to have it that way and so are the behaviour patterns associated with death. “Birth, living and death”, the three phases of life are extremely complex processes, the secret of which are still hidden within the black box of ignorance that humans carry as a privilege. There is also a phase in between—the disability phase which is the entry point of the event horizon of death or the exit point

of life from where life can still swing back. The disability phase is “gone time” that may deflect to living to count again. Humans and other life forms just go through all these processes as natural (that is the evidence) without being aware of the causes and designs. They are programmed and conditioned that way—not to be aware of the eluding complexity. Humans can procreate life in the natural way as they are programmed by default. The living has to die for the life to continue. The continuation of life is the prime motive for life sustenance, not that of the living. That means life is not for the living but for life itself as a natural design. That is why the living has to take care of themselves through cooperation and governance.

Formation of new life out of life before its visa expires is what the author calls reincarnation or rebirth. The life form is alive and healthy to some extent when it “reincarnates” as the offspring with some add-ons and take-offs. That is reincarnation applicable to all life forms in their living sense. No human or other life forms can be “recycled” as the same or another through or after death; simply, because, well, that is not necessary to discuss here. That is the law of nature. These are for explanations to the initiated about life—humans, especially where intellect is the survival tool. In reality life is much complex to explain.

Nature strictly follows the rule of needs and wants to be called as nature by the sapient world. It is also impossible for a human to design and manufacture or build another even if given all the 59 elements that go into constructing a human life.¹ It will not cost much to build a human external to one in terms of raw materials. Even a poorly paid author can afford to buy those elements. But humans simply cannot do it like they make other products.

Life is built by the life before it by a default process. That is the mystery of life at the moment. The patterns of human behaviour towards and associated with death change from individual to individual and group to group. They depend the way people are conditioned about death in their perspectives. This is important for a government to know while managing anything associated with death, not health security alone. The root of all about health remains in the outlook and certainty of death.

Death is the most beautiful and amazing aspect of the techniques of creation of life—the ultimate in design, something very much beyond human capability. The capability of human beings to create life in a test tube with death as the accompaniment is not a thing of marvel when compared to the original. Human effort, if possible, will be a kind of violation of the copyright of the forces of creation that possess many superior capabilities. Every life on earth comes with the certainty of death. The design of a life without death, the concept of immortality, besides being crude will be catastrophic. There can’t be a bigger curse or penalty than a judgment, “sentenced to immortality by life”.² In any case such a thing, life without mortality,

¹ Bryson, B. (2019). *The body: a guide for occupants*: Transworld Publishers, p. 2.

² In the epic Mahabharata War, Lord Krishna punishes (curses) Ashwathama also known as Drauni, son of Dronacharya and Kripa, with unconditional immortality for committing the dastardly heinous crime of killing the five sons (Upapandavas) of the Pandavas in their sleep. It shows among other

is impossible according to the law of nature. Life would have been delayed till the forces of nature perfected the design of death.³

For humans, death is not an acceptable overture. Death is feared. They like to forget it. The views on death are also different. For some, it is the grand ending orchestrated by the forces of creation. For others, it is giving way to another life. Yet to some, it is the beginning of another life. It does not end there. It is as eroticised as it is feared.⁴ There are many who love to die by taking life. Death is very dear to them. There are others who are forced into it, like the militants. For the Japanese samurais, death was the way of life.⁵ They followed the *Bushido*, meaning the way of the warriors where death is not a fear.⁶ However to keep the mind from the fear of death, it needed to be reminded repeatedly in various ways of the warriors all around the world. It is practised by the militaries today. The basis of acceptance of a harsh reality lies in belief systems. What is evident is the fact that normally people cannot accept death in reality unless supported by rationalised belief systems. The fear is hidden. A militant is told and made to believe he or she could reach heaven straight in one shot, no overstay or transit anywhere. Another way death is accepted is in the coping behaviour of bereavement of those who died. While coping with bereavement has all kind of consolatory behaviour patterns, including grief- and guilt-effacing rituals, the reality of death is also tucked away in some corner of human life and deliberately from the conscious mind. It is this aspect, “keep the death away” syndrome, that leads people towards health addiction. People wanted to be healthy, because they do not want to be reminded of death. Health and death are strange bedfellows. They cannot be compared. Health is not the absence of death; it is the guarantor of good living as long as alive. But deep in the social subconscious, health security originates from the fear of death, though it is considered to be a state of “not being sick and tired”. Health security will be quite demanding at times for a government concerned about national security. Tough it is actually not; death is for all time linked with health in human perception and belief. Hence, health security is also a curious case of keeping death away, of course, temporarily.⁷

pointers that death is a must to life fulfillment. The absence of death is a punishment. It can also be interpreted that terrorism (1) is based on the leading to revenge, (2) is the strength of the weak, (3) will not yield decisive end result and (3) hate crimes surpass punishments that humans can award (Ethnic security, Chap. 20).

³A term used in Indian scriptures for immortality in a positive paradigm is *chiranjeevi* meaning a person without death. This study concludes the person will be remembered for ever and not physically immortal as there are many evidences in the scriptures about the inevitable death for any life form. The term also explains the passage of time irreversibly as history, legend and myth explained earlier. A *chiranjeevi* turns out in the mythical dimension.

⁴Nuland, S.B. (1993). *How we die*. Chatto and Windus. p. xv.

⁵Sparling, K, *The samurai ethic and modern Japan—Yukio Mishima on Hagakure*. Charles E. Turtle Company. pp. vii-x.

⁶According to *Bushido* the only solution to bad and violent people are good people that are more skilled in violence. The factor and acceptance of death is hidden in such statements.

⁷There are genetic engineers who say “Death will be optional and ageing ‘curable’ by 2045”. *Dying* will be ‘optional’ within just 27 years and the ageing process will be ‘reversible’, according to two

19.1.1 *Life, Death and Health in Between*

The *raison d'être*, the *ikigai* or simply the reason for life is life itself.⁸ Though life is real and biophysical, it has a philosophical tone (Box 19.1). There can be a million and more expressions about life. People find life a painful drudgery. They try to rationalise it all the way. A close look at such rationalisation statements will show they are the creation of intelligent, but vacillating thought processes. Humans get into vacillating and self-cancelling thought processes when they rationalise. “Life is beautiful”, “life sucks” and a host of other explanations, eulogies and impertinences are based on individual perceptions and misconceptions of life at varying situations. Important and oft repeated among them is the “death is certain” statements like a whine of agony, which may be put in different ways according to the literary insight of the individual. “One has to die if born” could be laced with “whoever it may be, whether a prince or a pauper”. It helps to cool off in the heat of life. Such statements justify life by the rationalisation of ensemble insecurity for a human to keep going till end comes unplanned.

Box 19.1: “Life. Be In It” and Health Security

“Life. Be in it” was a popular health promotion slogan created by the government of the state of Victoria in Australia in 1975. The campaign was aimed to increase physical activity and general well-being among Australians and encourage them to take control of their health. The slogan created history in Australia. The author prefers this slogan as a great *en masse* motivator that showed concern for health security by a government more than half a century ago. The campaign was developed by the Monahan Dayman Adams advertising agency. It involved community announcements on television, cartoons in newspapers and community-based programming. The author considers the slogan the ultimate in prompting healthy physical, mental and emotional life.

But all said this study doesn’t believe life is a good thing to happen. Life is quite difficult for humans blessed with the intellectual bearings. Otherwise they don’t have to talk about the drudge by dredging the non-existent existentialism. It is as good as getting shored and abandoned on a strange beach after 2 months playing hide and seek at sea in a human smuggler’s rickety boat with a host of strangers—worse for a women though more advanced than a man by design. “What next?” becomes a

genetic engineers during the presentation of their new book in Barcelona. <https://www.google.com/search?client=firefox-b-d&q=death+will+be+optionalby+2045>. Accessed 20 September 2020.

⁸The author doesn’t support the idea of the “purpose” of life. Life is a happening, a continuum of sorts. That is why the author states life is indestructible in human form (Chap. 32). If it is created, it is not with a purpose like a kitchen knife or a drinking fountain. Therefore all what one has to do is to “live” life. If there is a purpose for life, then it should be life itself. The 1975 catch phrase by the Australian tourism, “Life. Be in it”, is almost close to this statement.

thundering soliloquy any moment in life in a chancy and uncertain world the moment one is born. It reverberates in the minds of the smiling parents also. Life has to be driven and steered on a road made exclusively for oneself that lasts as long as one lasts. But the damn thing has no brakes! Notwithstanding the collisions, mishaps, heartburns and whatnots, humans have to rationalise life and every action associated with it for balancing intellectually. They may, if required, find comfort in another statement exclusively made for them in this study: “There can’t be life unless death is assured”. Yes, everyone needs to produce the return ticket guaranteeing return while applying for visa to be born into life. It’s a short trip.

While death ends a life, birth is not the beginning of a “new life” or any extension of the “past life”. Birth is relayed continuation of life of the individual life form. In its natural process, life originates from an already existing life form that is not dead.⁹ It is the intriguing fact of life. The lives around are not new. They may be modified by evolutionary timeline, but as lives they are not changed in form and shape. They are old and created from old. All these are fine-tuning statements and not philosophically or theologically placed. It is simply the result of the organised way of nature in which one life is born from another and concludes at death never to return. It is this continuum of life that is amazing to the author. It means life doesn’t need any kind of supervision to continue. The original laws approve life and its continuity by default. That means God can take a vacation. If there is anything a government can learn from God, it is how to put governance in auto.

It will be interesting to incorporate this idea, the idea of continuum process, in theories of management and governance. Within the amazing continuum theory, there is another mystery waiting—every human form that was ever seen on earth was different from the other, and every human form that will ever come on earth will also be different from each other, though it will carry the signatures of their origin, being born from the old, all the way. Isn’t it a bit confusing? No, it shows there is no assembly line in human production.

Death is an intricate and extensively complex process. It is the concluding part of life. From the perspective of death, it is beautiful and orderly when the curtain begins to drop or when the countdown starts. Life ends for life to continue. Immortality is inferior to mortality. It simply means that, if the technique of death were not mastered in creation, there would not have been life at all. Life would not have come without death inbuilt into it. Death is an intricate and extensively complex process.

Life culminates in death by the process of ageing in the natural way. This process of life and death is the ideal situation. To that extent, the life of an individual is a closed system. The entropy increases at varying pace, maximising in the death of the individual. And according to studies, every human death occurs differently from that happened before.¹⁰ It means each human being has his or her own “designer” death

⁹There are reports that a dead man’s motile sperm contributed to life; the sperms were alive.

¹⁰Nuland, S.B. (1993). *How we die*. Chatto and Windus. p. 3.

at the end of it all, just like the biometrics. The death signature of each individual human is different even if the cause is identical.

Yes, that sounds a bit weird, but is somewhat fine for mortals. In fact, as mentioned earlier, one won't get a visa to enter life unless the return ticket is held under assured return. Or one could even say "death is the ultimate objective of being born". Well, it doesn't sound real. The expression is a kind of absurd philosophy but still valid to some extent. Against this background one can conclude, rationalise or philosophise many home-made points—that life is short; it can't be good unless one makes it that way with intellect, the survival tool that comes with it, users' manuals of various kinds and so on. All these show death is not a matter of sheer health. One could be in excellent health and still kick the bucket. But keeping life out of death's way is very much an objective of health security governance. Life rides health while galloping or striding towards death. Health security can extend the life span.

Health is a different game by itself. Though an in between paradigm between life and death, it is better not to link health with life and death for governance, where the objective is well-being in life. Humans are considered to be healthy if they meet the basic minimum parameters to survive "healthily" as prescribed clinically. That is when they can perform their physical, emotional and intellectual activities as prescribed and appropriate. It is a state of physical, mental and social acceptance in which disease and infirmity are absent.

This could hypothetically mean that even health (the living life) could have an exclusive signature for each individual where the factors of health applicable to that individual might reside. That means each life could be unique in life and death and its in-between paradigm—health. It also could mean that the prescription for good health for one may not be the right one for another. That impacts collective health security.

However, a definition for good health is not easy to conclude. It depends upon what is considered normal in a person's behaviour with respect to a situation at a particular time. A physician decides otherwise. Primarily such decisions will be based on medical tests carried out on an individual. The World Health Organisation (WHO) defines health as a state of complete physical, mental and social well-being, and not merely the absence of disease or infirmity (1946).¹¹ In this book, a diversion is made by replacing the term "social" with "motional".

Whatever one does about health or a government asserts in health security, death sneaks in finally in every one's life profile; blood circulation ceases and breathing stops—the two criteria necessary for a medical practitioner to pronounce human death.

The process of life and death was not completely understood by those who are dead or alive today. But the efforts are on, and signs are there that the search will continue, perhaps, more vigorously than before. But the process of ageing is understood to the extent that, in an ideal situation, death comes naturally to life.

¹¹ Taylor, D.J. Green, N.P.O and Scout, G.W. (2002). *Biological science*. Cambridge University Press. p. 495.

What lies behind the secret of mortality, the biggest event in the span of a life? There are various theories that attempt to explain the mechanism of ageing. One of them is about the accumulation of flaws in the process of body cell propagation. As and when body cells reproduce, they tend to get flawed, and these flaws are accumulated leading to ageing. This is the flaw in genetic information. Another theory is that it is programmed into the cells, leading to natural destruction under a biological clock. Yet another theory is that the body of an organism slowly loses its ability to defend itself and gives away at the end of it all to harmful organisms.¹² Well, the world doesn't know, at least not yet. But, in this case, is it really necessary to know who made the cookies if the requirement is to eat or gift them? If the idea is reversal, the humans should try it in other arenas how entropy can be reversed in much smaller systems—like running a car on the first fill of fuel again and again. Is it possible? It's not, but why don't decelerate entropy? After all it is a vector.

Life, originating from the living “old”, has a span before it meets the end. The average life span was much less in the early days. It was 35 years, two centuries back. Today it stands highest at 80.¹³ There are many reasons to the increase of life span in humans: Advancement in medicine and healthcare are quoted as the primary reasons.¹⁴ Whatever it may be, is there a possibility of the doubling game going on endlessly? According to some, people would have live beyond 150 years in a normal situation under good healthcare. In certain circles it is believed that the life span may extend to 300 years or so by genetic modification.¹⁵ But it did not happen. The laws of limitations have their own parameters for balancing the system.

Such cries apart, death is part of life, but its characterisation is different in human apprehension from that of the other life forms. Death just extinguishes life at one fine moment. It is not external to life, but internal. It is only the human who finds it difficult to cope with death and considers it as a different theme by itself and totally denies it. It is a mystery when it happens. The denial is strong. Acceptance comes very late. The process of dying is rooted in everything that a human mind is capable of concocting. Death and dying come in many different ways. Each one is unique in its biological and clinical reality. Whatever it may be, there is a lot of trauma attached to death. Bereavement is a terrible feeling. None of them recognises that the emotional scene of death is actually a passage way decided by the law of nature and there is nothing extraordinary about it from the point of creation, except the awe in the wonder called mortality and degradation—the most complicated and perhaps the ultimate in any design.

¹²Sharma, M. “Getting a Life.” *The Times of India*, Delhi. 15 November 1997. p. 12.

¹³Ibid. However according to the WHO's *World health report, 1998: life in the 21st Century—A vision for all*, the global life expectancy at birth in 1998 was 66. It is expected to reach 75 years by 2025.

¹⁴It could also be because of revitalisation of genetic signature by advancements in cellular process in an evolutionary programme that makes the progeny more advanced than the progenitors.

¹⁵Sharma, M. “Getting a Life.” *The Times of India*, Delhi. 15 November 1997. p. 12.

Amplifying the concept of death so far is with the intention to drawing the attention of the informed reader to the concept of life—the intermittent span between birth and death. It is in this inter-period the idea of health survives. Health is related to life more than death, which actually is a co-rider. Health is parallel and relates to being with life interspersed with everything that it is doing. In human beings, health is the state of an individual's ability to remain physically, mentally and emotionally,¹⁶ thereby socially, balanced by coping with the environment till the end comes naturally, the preferred choice in health security. Health is bad when there is continuing disease, physical deficiency and weakness and poor mental and emotional balance that make a person unable to cope with the environment and society comfortably.

It was the social revolution of the 1940s that introduced the principle of welfare state. The welfare state identified poverty, ignorance and ill health as the major issues. They are also related to three of the elements of national security identified in this book—food security, informational security and health security. The rise of modern medicine as the formula for eradication of diseases began in the nineteenth century and the French chemist Louis Pasteur's (1822–1895) attempt to correlate specific microbes with diseases. Health under his doctrine became increasing the resistance of the body to cope with diseases. This is a turning point in the perception of health. The body becomes the weapon against diseases from then on. Physiological conditions are to be favourable for natural resistance. The advancement of medical science now relies on the understanding of the human body from its molecular and biochemical aspects merged into its genetic signature.

So, what is health that health security looks into? It is already said they are the physical, mental and emotional aspects of its people, at least for now. But the topic is about wholesome health which comprises all the three. But it is important to know that they are all contained in the human body and not standing alone. In this aspect the physical health should contain mental and emotional and emotional health should be an area of mental health like a Russian doll. That's how this study recommends looking at health governance. The separation is only for governance purpose as they are entirely different. But for health purposes, it is all about the body to which the mind including the emotions belongs. For this purpose the mind is the neuro-intellectual path, and emotions are those that guide the behaviour patterns at the end. It means physical health is about the health of the physical aspect of the body including the neural systems. Mental health is the health of the neural system.

There are various conclusions on the typology of health; it includes physical, mental, emotional, spiritual, occupational, social, environmental, and intellectual. Interestingly some people also include financial health among them. It is just an

¹⁶Under health security emotional health is considered as part of mental health at the macro level of national governance. Mental health is about processing information, whereas emotional health is about the expressions of feelings. But both have to go through the process of neurons and the neural systems within the body. Hence divisions are for convenience. This book sees health as physical, mental and emotional and accepts that mental also includes emotional aspects (see box at Sect. 19.1.1.3).

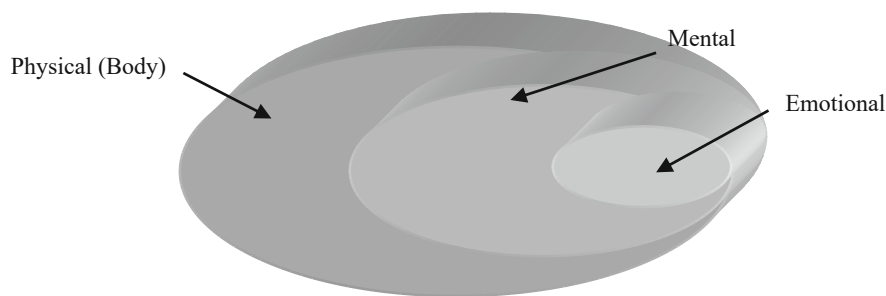

Fig. 19.1 Health and health security matrix (hypothetical)

expression in money matters. For a government, health security is about the human body and the brain, and all those associated with the neural systems as part of the body. The subdivisions into mental and emotional are for convenience.

Health security, as an element of national security, is concerned about the physical, mental and emotional (PME) health of the citizen. All of them are the aspects of the human body with a mind and associated emotions. Every other type of health falls under them from the point of view of governance (Fig. 19.1). The diagram is hypothetical because the three types shown are inclusive and cannot be separated. They affect each other and are not only awesomely intertwined but also interactive with the human systems the individual is in. That is also one of the problems in governing them.

19.1.1.1 Physical Health

Physical health is the condition of the human body at a given time. Though the body comprises the neural system, physical health as a term is expressed sans the mental aspects of the neural system though they are closely interconnected. Physical health takes into consideration all factors, including the absence of disease to fitness level that provides the overall feeling of wellness to a person. It is a critical factor adjusted to age for human activity. Physical health is affected by many factors in a person's life including genetic signature, physical activity, food and nutrition intake, mental and emotional stasis and above, perhaps all, balanced sleep and body cycles. There are many examples of physical activity that range in levels of intensity from light to vigorous. Natural ageing is not a physical disease. But ageing population is a governance issue.

19.1.1.2 Mental Health

Mental health is the absence of mental illness and neural disorder. Mentally healthy people can function and perform the desired roles in their social and individual lives satisfactorily by adaptive and adjustable behaviour. Mental health projects cognitive,

behavioural and emotional feeling of wellness. Various psychological factors contribute to mental illness. They include various childhood traumas and downbeat conditioning.

There are various mental illnesses and disorders. They include the following:

- Anxiety disorders
- Personality disorders
- Psychotic disorders (such as schizophrenia)
- Eating disorders
- Trauma-related disorders (such as post-traumatic stress disorder)
- Substance abuse disorders
- Anxiety disorders
- Multipolar affective disorder
- Depression
- Dissociative disorders
- Eating disorders
- Obsessive compulsive disorder
- Paranoia
- Learning disorders and so on

19.1.1.3 Emotional Health

Emotional health is associated with the brain and mental health in developing personality appropriate to the age that leads to the ability to adapt and adjust with personal and social circumstances and interactive behaviours (Box 19.2). Personality is the behaviour pattern at a particular time in a person's life. Emotional health projects confidence in a person. The person will be positively sentient. Emotion is a state of mind associated with neurophysiologic changes governed by thoughts, feelings, behavioural responses and other aspects. Emotions are linked with the basic survival necessities in a human created by the brain cells—fear, feeling of pleasure and contentment, gloominess, surprise, frustration, angered and so on—and the way a person is cognitively balanced to manage them in all situations without dissonance.

It is the view of the author that emotions cannot be tested or measured under artificial or simulated situations. They are real and keep changing in short periods, sometimes totally opposite to what happened earlier. They are beneficial and harmful depending upon the interactive situation. Emotions are cooked in the brain, hence loosely related to mental health. But in the modern world, advancing at breakneck speed, it will be prudent to consider emotion separately for governance. Emotional health of decision makers is a critical factor in governance. Unlike physical or mental health, as explained earlier, emotional health will not be visible easily as it occurs only at situational change. And also it can change in a jiffy like a storm that veers off. Hence the emotional responses from people cannot be easily predicted.

Considering emotions are brain games, research on brain cells and neural systems associated with the generation of emotions in the past had concluded many false premises. Two of them are as follows¹⁷:

- Each emotion is located in a specific part of the brain. For example, the amygdala (part of the limbic system, which plays a role in processing emotional reactions) is supposed to be the “fear centre”.
- When the right stimuli are presented, a specific emotion is triggered, accompanied by a fixed facial expression.

Emotions come out of the brain as it is processed by it and transformed as behaviour based on past experience and sensory perceptions of the body.

Box 19.2: Is Emotional Health Separate From Mental Health?

No, not according to this study. Emotional health can be affected by mental ill health. Therefore emotional health is more a part of the mental health than an exclusive mental paradigm. But it is taken separate for mental studies and treatments in this book. Therefore till such time a considered opinion is generated and practised, emotional health is treated separately from mental health.

19.2 Health Security: Setting

Health security, from the national security point of view, obviously cannot accept the principle that it originates from the fear of death. Neither the concept nor its provider, the government, is a guarantor of immortality. It is a process that aims at keeping the people in healthy comfort till death. It contributes to their well-being and, therefore, an element of national security interrelated with others that contribute to national security. The WHO issued more clarifications in 1986 on health stating it is a resource for everyday life, not the objective of living. Health is a positive concept emphasising social and personal resources, as well as physical capacities.¹⁸ Health, according to the WHO thus becomes a resource available to humans to pursue their social obligations and quality life styles.

Health is not an end by itself. In a definition in 2009 by Lancet, the medical journal, health was stated to be the ability of the body to adapt to new threats and infirmities.¹⁹ The important aspect of health security is not in the definitions but in the types of health which are primarily two: physical and mental. Mental includes

¹⁷Noldus information technology. Behavioural research blog. <https://www.noldus.com/blog/how-emotions-are-made>. Accessed 12 December 2019.

¹⁸“What is good health?” https://www.medicalnewstoday.com/articles/150999#what_is_health. Accessed 23 May 2020.

¹⁹Ibid.

emotional. Humans use the term emotional quite frequently in conversations. It's chic and sounds better. Health scenario of the world is constantly changing for the better. But there are more and more diseases and other physical problems surfacing today. Changes in the health culture are induced by modified lifestyles, population pattern, increase in life span, advancement in medicine, awareness among people, etc. More so there is the nature's way of uplifting life evolutionarily. Nature is a full-time house keeper in maintaining life by cleaning the unwanted and making the wanted remain healthy.

People look up on a healthy nation and expect the government to provide for healthcare facilities. This expectation is at the core of health security concept. Most of the people view health security under egalitarian principles—equality for all, whether rich or poor. For the government, it is a question of providing for all, but the system is centred on those who cannot meet the mounting expenses of medical treatment. At the same time, health security is not about providing healthcare alone; it is beyond that.

Health security perception leads to all aspects of health and not just treatment of illness. Healthcare as a medical provision is incidental to health security. What matters is keeping the people physically and mentally healthy by all available means. Preventing disease is part of it. Health security, as an element, is about maximising physical and mental including emotional health of the people of a nation within the acceptable parameters of national security maximisation.

Health security involves cost to the government. Cost of healthcare and effectiveness of medicine are social contentions. Health cost, driven by various forces, is increasing at a staggering level around the world. Health improvement is disproportionate according to critics. Health security is not all about medicine and physicians. It is correlated with food security, environmental security and other elements of national security to a considerable extent. That is why health security, which is beyond medicines and physicians, has been considered as an element of national security. Ultimately it is the body with the mind inside the designer of one's personality and projector as well as assessor of one's health.

19.3 Concerns of Health Security Governance

Health security, from the national security point of view, is about keeping the people of a country healthy within their programmed life span. It is about the quality of physical, mental and emotional life that a citizen can aspire for. Effective health security, therefore, calls for protection against all known threats to physical, mental and emotional health of the people of a nation. The environment is a factor that is closely related to health security. Bad environment causes poor health in every respect. Human beings have to balance ecologically, and the ecology has to be compatible with the people. This balance is constantly in danger by human activities and the vagaries of nature. The environmental component of microbial diseases is another factor. The relationship of environmental security and health security is a vast area for investigation. Environmental factors that affect health security can be varied. Identified factors are as follows:

- (a) Lack of access to fresh water
- (b) Lack of access to nutrition
- (c) Unhygienic environment
- (d) Indoor air pollution
- (e) Urban air pollution
- (f) Agro-industrial pollution
- (g) Closed in human population
- (h) Density of population
- (i) Use of fossil fuels
- (j) Deforestation
- (k) Forest fires and smoky and cloudy environment
- (l) Change in climate
- (m) Disasters
- (n) Food contamination by environmental pollutants, chemicals and microbes
- (o) Close domestication of animals and zoonotic diseases
- (p) Environmental depression
- (q) Environment restricted lifestyle

There are more. The diseases that are caused by environmental factors are far too many. They are related to deficiency diseases (anaemia, rickets, beriberi, etc), arthropodal and helminthic diseases (malaria, filaria, etc.), communicable diseases (dysentery and diarrhoea, tuberculosis, etc.), and non-communicable diseases (cancer, cardiovascular diseases, etc.). The geomedical approach to health security identifies these diseases and their relative cause based on environmental degradation. Diseases are classified in many ways. In a cause-based classification, diseases fall under seven categories. They are as follows:

1. *Caused by organisms.* Identified disease-causing organisms are viruses, bacteria, rickettsiae, protozoa, fungi, flatworms and round worms. They enter the human body through various agents and interfere with its functions.
2. *Human induced.* They are induced by the human systems. They are also called social diseases—coronary heart diseases, alcoholism, drug abuse, lung cancer, domestic and industrial accidents, industrial diseases such as asbestosis and pollution-related disorders fall under this category.
3. *Deficiency diseases.* The absence of certain nutrients in diet causes deficiency-induced ill health. For example, protein deficiency can cause kwashiorkor²⁰ and marasmus.²¹ Vitamin and mineral deficiency may result in many ailments.

²⁰Occurs among young children because of protein deficiency. Kwashiorkor is characterised by oedema and enlarged liver with fatty infiltrates. There may be sufficient calorie intake but with insufficient protein consumption triggering kwashiorkor.

²¹Undernourishment causing a child's weight to be significantly low for their age, reducing the body mass index (BMI) to a dangerously low level. There will be acute loss of body fat and muscle tissues.

4. *Genetic and congenital*. These are present at birth. Cystic fibrosis, Huntington's disease, etc. are examples. Here the information required is for babies with genetic disorders and managing their birth under ethical controversies.
5. *Aging and degenerative*. Degeneration of the body tissues in the natural process of ageing.
6. *Mental illness*. A wide variety of disorders exist: Schizophrenia, senile dementia and depression are a few common mental ailments.
7. *Emotional shortcomings*. Emotional shortcoming is a serious matter in the modern world. It makes a person unable to cope with the social demands of life and society without conflict. Emotional health is a vital requirement for those who are involved in national security management. In country it means everyone since people participation is an ingredient of NS_{max} .

19.4 Public Health

Public health is about the health of the citizens of a country. Health security element is primarily concerned about public health. The concept of public health originated around 1830 during the industrial revolution in the industrialised nations. Public health is the art and science of preventing, preempting and controlling disease; prolonging quality life; promoting physical, mental and emotional health; meeting sanitation; ensuring personal hygiene; controlling infection; administering health and providing services. There is also community action in the promotion of health and prevention, preemption and treatment of diseases. Community measures in healthcare were also there in the ancient world. It was found in the remnants of the Harappan civilisation that flourished in 3000–1500 BC.²²

The practice of public health is concerned with primary healthcare that includes medicines, diseases, community, housing, hygiene, water supplies and food. Public health medicine is part of the greater enterprise of preserving and improving public health. While community medicines deal with habitability and lifestyles of the people, occupational medicine is the specialised part of public health medicine concerned with health, safety and welfare of persons in the workplace. Public health management needs special methods of information gathering (epidemiology) and corporate arrangements to act upon significant findings and put them into practice. Statistics collected by epidemiologists attempt to describe and explain the occurrence of disease in a population by correlating factors such as diet, environment, radiation, smoking, tobacco chewing, etc., with the incidence and prevalence of disease. There should be regulatory aspect of governance related to water supply, food processing, sewage disposal and treatment, air contamination and pollution. Governance also includes control of epidemic infections by means of enforced quarantine and isolation to prevent and contain infectious diseases in the community.

²² Mahajan, B.K., and Gupta, M.C. (1992). *Preventive and social medicine*. Jaypee Brothers. p. 1.

Public health management involves complex decision-making. Often it gets involved in political skirmishes. A new government may undo what the previous government has done involving considerable wastage of public money. Health service resources are limited. They are to be allocated to a large number of people. Though the process of health planning has improved all over the world, there are many countries that do not have primary healthcare facilities for its people. National health planning requires close involvement and coordination between all agencies concerned with health management. Though there is awareness at national and international level, the general opinion world over is that little is being done in the approach to public health. The need of the day in health security is to eliminate diseases. All spheres of life impinge upon health and, therefore, inter-sartorial planning for health is necessary. The parameters include air and water quality, control of child and old age mortality rate, worsening of health and social indices of the conglomerations.²³ While governments take efforts, the utility of such measures can cause problems because any measure on public health can have an effect on public satisfaction. In Europe, public health arose as a special area of activity in the mid-nineteenth century. In industrialised cities, with the realisation that the health of one particular section of society was closely bound to that of the other and that of each section, public health was determined by the conditions of life. Improving the abysmal living and working conditions of the poor was undertaken, realising that these lead to rampant malnutrition and communicable diseases and also posed a threat to the health of the better off through epidemics and social delinquency. The care on the poor was with an eye on the health of the rich who were scared of communicable diseases. Healthcare in a society is not quarantining the rich and the healthy from the sick and the impoverished. It is quarantining the world from sickness. This psychology, care for the sick to prevent the healthy from getting sick, is perceived as the underlying principle of health security when viewed from an acute angle. Is that the right approach in healthcare? The perceptions may vary, though. Some of them may be politically or commercially driven. Concerns expressed by governments on epidemics and pandemics may follow perceptions that may have one or more driving forces behind them. Isolation is the traditional choice to protect the healthy from the sick. It is often more costly in its opportunity expenses than facing it by treating the sick.

A decision on health services development will have to be decided early and should centre on the people. That means everybody. Healthcare should be available to all irrespective of their ability to pay. At the same time, it should highlight the areas that need attention on a priority basis—for example, women's health and gender sensitisation, if and where it is neglected. There is a feeling in the public that simplistic single-pronged technology-driven programmes have never fulfilled their promises.²⁴ Primary healthcare should be based on an adaptive policy concerning all involved. It is not just treatment alone but a holistic approach to

²³Priya, R. "The Two Faces of Public Health." *The Times of India*, Mumbai. 12 April 2001. p. 12.

²⁴Priya, R. "The Two Faces of Public Health." *The Times of India*, Mumbai. 12 April 2001. p. 12.

health security. The basic ideology revolves around various activities that include the following:

- (a) Inculcating awareness about the state of health and methods to improve health aspects in public
- (b) Food and nutrition management
- (c) Drug management
- (d) Ensuring availability of safe drinking water
- (e) Emphasising hygiene
- (f) Maternal and child healthcare availability
- (g) Immunisation of people
- (h) Elimination of locally endemic diseases
- (i) Provision of essential drugs
- (j) Trauma centres
- (k) Family planning and advisory centres
- (l) Common disease treatment centres
- (m) Accident prevention
- (n) Dangerous disease awareness
- (o) Sex education
- (p) Eradication of superstition in health security
- (q) Disaster recovery centres
- (r) Emotional health development centres
- (s) Distress and anxiety awareness centres

The list can go on further based on cultural and economic differences of people of different countries as well as within a country. Public health deals with a variety of topics within the health security concept. Preventive medicine, social medicine, community medicine, etc. are all part of it besides various other topics. To that extent, health security is a much wider subject that may go beyond the world of medicine and associated subjects. Besides spurious drugs, even administration of drugs needs to be done carefully. In public health management, a major area of negligence is from drug administration. Practitioners are aware that most of the drugs are more or less toxic in some aspect or the other, but need to be administered regardless, since the question is relief from a particular disease in medical management. The world is full of drugs and drug manufacturers. It is a world where everyone in the business likes a “good” disease. In fact there are many times more drugs than the number of diseases. It is proliferating under constant competition and purely under business objectives. The risk, therefore, takes a side seat. There are also diseases without identified drugs. Here the competition is to identify a drug. It is not disease, but competitive business interests that drive drug design. That has been a boon in a different way to health security and could be better steered in the process of maximising health security.

The general tendency is to assess public health development in terms of so many doctors for so many people. The number of doctors cannot be a clear indicator of health security. There are many people who are ill in the hospital who would not have been there in the first instance—by prevention under effective health security schemes. Having a doctor at every corner is not health security; it could indicate the

lack of it. There are many diseases, and those created by the hypochondriacs are what any doctor will dream of. Because such diseases just vanish by the time the doctors get paid. There are hosts of health people who thrive on ordinary diseases of people or their anxieties related to health. Alternative medicine doctors, pseudo nutritionists, spa managers, faith healers, self-made food experts and assorted quacks belong to this category. But, still, diseases persist. And they will, as long as there are money and healers in every colour and shape available around. Medical experts say that doctor visits can easily be overdone. In fact, in most of the visits, a doctor will have nothing much to offer except acting as a relief psyche and getting paid for it. Most of the symptoms and diseases of the modern world are self-limited. Such diseases get cured without doing anything in nature cure labs. Self-limited diseases are those that will go away after certain time in a well-managed health security system that will have an eye on cost at government and individual levels.

19.5 Health of the World

A spread out medical or health investigation and survey will show that the world is not in good shape. It was never. The future is unpredictable. This is the scenario the governments of the world will have to appreciate, face and challenge, if the objective is to make the globe healthy—physically, mentally and emotionally. Is it possible? Yes, this study believes. Will it happen? No. The biggest folly of governance is the trust deficit between the government and the people. This is attributed to the political system and the associated gimmickry of most politicians in their survival rush. It is not as much as one thinks. The real reason is human limitations in listening and comprehending reality. They are not tuned for that at this time. People have limitations in analytical thinking, asking questions that will lead to reality and factuality appreciation and, above all, communicating. Hence there are problems in getting people understand and behave. Health security is one of the elements of national security that is affected seriously by this attitude of citizens and governments. Politics, business and associated games and absurdities are secondary. But this can be resolved by governance. A healthy population reduces health risks and thereby maximises health security.

Though the state of health of the global population was never satisfactory, there is progress all around. It could be improved if the world is taken as a whole system of human community. In such case managing health will be easier. But it cannot be managed that way except for monitoring by international organisations under the current context of nation states. Health today is still a country-specific subject. The health scenario of the world is not uniform. It is appropriate to the state of a nation and, therefore, a study in contrast. In all circumstances, the scenario will remain that way with widening gaps in the health security of people. There are countries where a child can expect to live a full and healthy life to its maximum life span comfortably with all necessary medical support, childcare, and immunisation programmes with guaranteed continuity. On the other hand, another child that is born in another country may not have a life span of the modern-day world average, but that of a

world two centuries back. The child will grow into an adult with all the diseases it can pick up on the way since it will not have any of the facilities that a more developed country can provide. This is an admission of the WHO in their annual reports more or less every year.²⁵ The range varies from no care to maximum care in various parts of the world. But every report of the WHO is on an optimistic note about the future. That is comforting, if not encouraging.

The health inequality of the world is growing, and more than the global community, health security can only be tackled by national governments concerned about national security. Unlike many other elements of national security, health security, therefore, is strictly international in application. The global community may attempt to reduce the gap in the meantime. That too will need the support of the national governments. The reason why health security is not uniform at global level is that it depends on many factors that affect it externally. Poverty, armed conflicts, infra-structural inadequacy, environmental instability, insufficiency of primary healthcare institutions, etc. that affect the health of a nation's population are actually outside the system of governance on health security.

A press release from the WHO on 4 June 2000 showed Japan on top of healthy life expectancy pyramid at 74.5 years. Sierra Leone is at the bottom at less than 26 years.²⁶ The survey was carried out in 191 countries by a new ranking system developed by the WHO. This was the first time the WHO used a different model called the Disability-Adjusted Life Expectancy (DALE). It calculates the number of years of life equivalent to "full health". Such presumption is on averaging the human life that may not be indicative of the full health life of an individual, but good for generalisation of the state of health of the population of a nation. According to DALE,²⁷ the top ten nations are Japan (74.5), Australia (73.2 years), France (73.1 years), Sweden (73 years), Spain (72.8 years), Italy (72.7 years), Greece (72.5 years), Switzerland (72.5 years), Monaco (72.4 years) and Andorra (72.3 years). An interesting point here is that according to this system, the female babies get more years of healthy life than male babies. For example, in the United States, the female baby has 72.6 years to grow up and enjoy a healthy life, whereas the baby boy has just 67.5 years. Russia is another country where the gap is high. It is 66.4 for female babies and 56.1 for male babies. The gap is wider in Belarus and Ukraine. It scores another point on the superiority of women over the male in life design.²⁸ Basically in the DALE system, a person "die" earlier and suffer disability for the rest of the time—till biological death, that is. The calculation is by weighting the years of ill health according to severity subtracted from the expected overall life expectancy to give

²⁵ www.who.int/whr/2003. "World Health Report 2003. Overview." 26 November 2004.

²⁶ www.who.int. WHO Issues New Healthy Life Expectancy Rankings, Press Release, 4 June 2000.

²⁷ Mathes, C.D. (2000) Global programme on evidence for health policy working paper No. 16. <https://www.who.int/healthinfo/paper16.pdf>. Accessed 13 June 2021

²⁸ A point of caution is that it is not true for every country that the baby girl has longer life expectancy. For example, as per the WHO report for 1998, a baby boy in Saudi Arabia has an average life expectancy of 65.1 years, whereas it is 64 years for a baby girl. In Qatar it is 64.2 for males and 62.8 for females.

the equivalent years of healthy life. The years lost in disability are substantial in certain countries. The loss is caused by injuries, blindness, paralysis and debilitating effects of diseases such as malaria. On the average, the loss by disability is about 9% in healthy countries and 14% in worst-off countries. The countries in the lower end of the DALE are Sierra Leone (25.9 years), Niger (29.1 years), Malawi (29.4 years), Zambia (30.3 years), Botswana (32.3 years), Uganda (32.7 years), Rwanda (32.8 years), Zimbabwe (32.9 years), Mali (32.9 years) and Ethiopia (33.5 years).²⁹ The reasons are basically rampant distribution of HIV-AIDS epidemic, poor development, killer diseases including cancer and coronary heart disease, chronic lung disease by tobacco chewing or smoking and high rate of violence in the sociopolitical national system. The reason for higher life expectancy is attributed to lower heart disease by following traditionally low-fat diet, low rate of tobacco-associated diseases and healthy lifestyles. But the life expectancy of the world is increasing gradually. It was 48 years in 1955 and 65 years in 1995. According to the WHO, it will be 73 years in 2025.³⁰

Table 19.1 gives the life expectancy of the world population in select countries by 2025 according to the WHO study in 1998.³¹

The report also states a large number of premature death in the world. It was 21 million in 1998. Causes of death vary from country to country. Predictions of leading causes of death for industrialised countries are heart disease, stroke and cancer,

²⁹Ibid.

³⁰www.who.int/whr2001. The World Health Report 2001, 26 November 2004.

³¹www.who.int/whr/1998. Trends in Life Expectancy, 26 November 2004.

whereas for developing countries, it will be infectious diseases, mostly HIV-AIDS and tuberculosis. Some of the developing countries that will follow the lifestyles of industrialised Western countries will succumb to non-communicable diseases. The cause of death ultimately changes the mode of lifestyle in human growth. In the order of seriousness, the leading causes of death in the world are infectious and parasitic diseases, circulatory diseases, cancer, respiratory diseases and others due to prenatal conditions. Serious problems exist with people who suffer from terminal and critically incapacitating diseases. Cancer is a disease still considered to be terminal. The productivity loss due to cancer extends much after the bleak chances of survival. Even years after surviving the critical disease, people can have their life totally in jeopardy with poor health and leading a lower quality of life.³² And so are many other diseases. The victims often do not have access to counseling or support.

The pandemic spread of HIV and AIDS over the world is a serious cause of worry for national governments and world bodies. Sexual interactions with affected individuals, sharing contaminated needles by drug users, using infected syringes in medical practices, etc. are causes of transfer. Children born to infected mothers are another group of victims. In some parts of the world like Brazil, prevention and care have been successfully integrated. Women are more susceptible to HIV-AIDS.³³ Access to antiretroviral (ARV) therapy can reduce the gap. The WHO advocates ARV therapy to AIDS victims. The goal is universal access to ARV therapy. According to the WHO, there are about 40 million people affected in the world as on 2000.³⁴ Global estimate revealed that 42 million people were living with HIV-AIDS in 2002. The fastest way of the spread is by birth to infected mothers. The disease had hit the sub-Saharan Africa the worst. Asia is fast becoming a death cauldron for HIV-AIDS personnel. The economic burden of affected countries on health security will jeopardise the whole system.

Small pox has been eradicated from the world. Polio has been pushed back, but still at large in many parts of the world. It is a killer of human productivity that makes the victims handicapped. It is amazing how with the will of national governments, killer diseases can be controlled; governments can restore hope in people by proactive healthcare objectives. Experts on health security call for a holistic approach. A judicious choice of pollution control mechanisms, alternative production, substitute products, etc. would reduce the need for relocation. Health activists in India note that treatments are becoming increasingly expensive as state cuts its expenditure on public health, and medical costs are spiralling out of the reach of even the well-to-do families in India.³⁵ According to the Centre for Enquiry Into Health and Allied Themes (CEHAT), even the routine treatment is becoming very

expensive in India where the government meets only 20% of health bill, while the remaining has to be footed by the individual according to reports. In the United States, it is stated that the government pays 44%, and in Europe it is 70%.³⁶ Only about 5% of the population in India is covered by healthcare.³⁷

Terminal diseases in a nation not only increase the life risk but also mount the bill for healthcare. There are other issues also that deals with health security—biological warfare, transnational epidemics, genetic modification, issues of hygiene and nutrition, etc. Anything that causes a dent in health security is a reason to worry, but AIDS causes panic. AIDS has killed 22 million already in the world. According to a study, the highest percentage of AIDS is in Botswana. Thirty-six per cent of the population is affected (2004). It has created a shortage of teachers, decimated the service sector and shut down local economies. AIDS has become alarming in Asia. In Cambodia, it is about 4% of the population. In India it is estimated at 0.5–1% (2004). If not dealt properly, India is in danger of suffering the fate of Africa, considering its population level. The obstacles in any country are legion: illiteracy, poverty and bad governance of the poor. Ironically, scientific advancement also can be a cause for dangerous health consequences. An experiment in life sciences gone out of kilter can accidentally lead to a killer disease. That is why strict control is required in all aspect of medical and associated researches.

The world will witness unprecedented increase in older population, whereas the growth in working age population will decrease. If the demand for the working age population increases, there will be movements across borders of young people. Old age personnel are also becoming healthy in developed parts of the world. Old age healthcare is said to be neglected considering a non-productive option. But it is an important aspect of health security that could be highly rewarding, if carefully planned. The contribution of the old age healthy people can be very substantial to a society as it can be seen from the biomodeling of a family. The role of a grandparent in rearing the young is very critical and can be seen from the Upper Paleolithic Moderns who pushed away the Neanderthals. It was based, if not totally, on the power of the old.³⁸ Today it is visible that the disability factor among the old is reducing in many parts of the world and they are able to live a comparatively healthy life. The efficacy of old age healthcare and productive use of the old and healthy could revolutionise the concept of health security, especially in nations like Japan where old age people are likely to be more. It will be a bold experiment for governments that have the potential to bring a major change in productivity with respect to age in demographic analysis. But according to the WHO, health may be improving on a world average, but many people are denied the benefits.

³⁶Dixit, R. "Healthcare Biggest Cause of Debt." *The Times of India*, Mumbai. 10 June 2001. p. 5.

³⁷Ibid.

³⁸Wells, S. (2002). *The Journey of man—a genetic odyssey*. Allen Lane, The Penguin Press. pp. 130-132. The act of child being cared by its grandmother is vital for human existence in a healthy manner since it has influenced human life at the earliest times.

Women, irrespective of their nationality and society, are comparatively low in health security and subjected to attitudinal problems by gender bias. Concern for women's health is tragically low in most part of the world. Women are more complicated by design than men. To that extent they are superior in design. The requirement of child bearing and rearing for human survival and existence makes them more compounded than men. Men's role was hunting from the primitive days. Women's role was much more sophisticated; they reared the family including their men with love and compassion. They cooked the game the men brought from the hunt and made their beds. This fact, however, is diluted in the hunter-man mentality world over. It leads to gender bias from the early days of the girl child. The girl child does not get the care the boy child gets in many parts of the world. The trend continues. And, surprisingly, even followed by women as members in a family or society. Still women survive. That is another proof of women's superiority over men in design and endurance for survival.³⁹

Next is one of the controversial questions posed by this study: Is the worldwide trend to neglect women hidden within a natural process? Is it required for the survival of men who are weaker and thereby balance the process of survival for both the genders?⁴⁰ It cannot be answered easily. Most of the issues, even if seen as deliberate in human life, could be by default in the system for its continuity. This argument can be visualised as hypotheses in the fertility capability of a woman controlled by the tendency for female foeticide or the superiority of women balanced by men's projected dominance that strictly is an allowed handicap. These are not tested hypotheses, though.

A re-look at this poser will show a visible model with arguments:

1. It is said women are superior to men by design.

The hypothesis is proven and accepted as true and positive. It is medically and genetically acceptable. Desmond Morris in his book *The Naked Ape* mentions about the superiority of women by design.⁴¹ While men were crude and brutally survival hunters, women were designed to be more sophisticated in rearing them. If women are of superior design for the role of life, then the assumption is that they would have overrun men in the world. It cannot be permitted from the existential point of view. It has to be controlled to balance human population with matching gender population.

2. *Three methods of such balancing are seen by default.*

³⁹Women's superiority over men can be undoubtedly established from their genetic design. The design also shows that they are less susceptible to diseases that often affect men. But there are many other diseases that may affect a woman by their sheer role performance. Hence healthcare has to be without gender bias.

⁴⁰Such questions originate from hypothetical adaptation of a belief that nothing that a human does is without a purpose. If that is so, they are programmed that way as a requirement for the survival of the species. Such programming, if true, has to be by default.

⁴¹Morris, D. (1967). *The naked ape: a zoologists study of the human animal*. Jonathan Cape Publishing

- (a) Women's productivity is less than their fertility capability (Chap. 11). This controls unprecedented population explosion. It cannot be said it restricts girl childbirth to match with the boy childbirth except from the theory that chances for girl children are more in any conception since XX is girl child and XY is boy child where chances for XX survival is more. In that case there is a regulation by default here.
- (b) The productivity rate is further reducing. This may be attributable to balancing the population as a whole.
- (c) The much-despised practice of foeticide in certain parts of the world targets mainly the female foetus. This is a criminal and ethical violation. But is it from a primary instinct of the unconscious?
- (d) Gender bias is aimed at providing better care for men. Is it necessary to keep the men healthy to survive, again by default in the psyche? Doesn't majority of women in the world accept the bias and feel comfortable under domination of men? Is it by an unconscious drive? Will a reversal of role in the absolute sense (though impractical) become mutually destructive to both men and women?

The entire hypothesis and its outlook projection is an analysis in a different, difficult and controversial perspective. The purpose is to see whether there is a necessity to have such differentiation between genders because one gender species is just tough and the other comparatively weak. Do they have to balance for mutual existence? There is no research on this subject. Do women stand to lose existentially just because they are superior to men in the design of life?

According to the WHO, of the 57 million deaths in 2002, 10.5 million were among children below 5 years.⁴² More than 98% was in developing countries. In certain parts of the world, especially in Africa, the child mortality rate is increasing. More than 35% of Africa's children were at higher risk in 2003, and the figure can go up further. The causes for child mortality are perinatal⁴³ conditions—lower respiratory tract infections, diarrheal diseases, HIV-AIDS and malaria with malnutrition as an added factor.

Radical reorientation in health systems is possible only if national governments take care of health security from productive angle. The basic theme is that if the population has to be useful, they have to be productive. Health—physical, mental and emotional—is basic to productivity. In this equation, what matters is not age but ageing. Ageing is not reversible, at least not yet, but uplifting health can reverse the effects of age with respect to productivity. It is very much possible under an effective health security regime.

The state of human health worldwide, barring some exceptions, needs improvement for increased productivity. The general state of the world's health is confronting too many problems. First of all, this is an aspect that is governed by natural forces of environmental factors of life and birth and hence not strictly under

⁴² www.who.int/whr/2003. Overview, 24 August 2004.

⁴³ Perinatal pertains to the period immediately before and after birth. It is defined in diverse ways. Mostly perinatal period starts at the 20th to 28th week of gestation and ends 1 to 4 weeks after birth.

the control of the global community. The national governments have a major role to play for which many nations may not be yet ready and the chances are bleak in the immediate future considering the instability of human systems. Ill health and mortality rates will increase. The killers will be HIV-AIDS and other known and unknown diseases waiting to strike. Added to this are injuries caused by various activities. Death by war, the way it happened in the First and Second World Wars, may not occur. A pandemic of the intensity of Black Death is also a remote possibility. But chances are that many will die and many will be sick, injured and handicapped in the future. Mental and emotional balance will also take a toll since it is directly related to the pressures of life. Depression is a major mental illness today. According to the WHO, depression will be the second most common health problem of the world by 2010. The chances of depression among women are almost twice that of men. It is one in five in women and one in ten in men. Children and adolescents also suffer from clinical depression.⁴⁴

Socio-econo-political instability of a nation can virtually forego focused health facilities for its people. Illiteracy, hunger and poverty, lack of health awareness among population, lack of access to clean air and water, gender inequality, environmental degradation, ethnic conflicts and war, etc. generally affect the programmes to maximise health security.

Healthcare to the scale of polio or small pox eradication in the world is a group activity that involves international organisations, governments, humanitarian organisations, private sector organisations and volunteers world over. But new diseases start surfacing in spite of eradication of the old affecting health and economy of unsuspecting nations. SARS (severe acute respiratory syndrome) is one of them. It is caused by a corona virus unlike any other virus in its family. Transmission is from person to person during droplet infection exposure by coughing or sneezing. In 2003, SARS spread out from the mainland of China and was quickly controlled, unlike in the past, with other killer diseases, though much damage was done in the short period it survived. There were more than 8000 cases in which 900 deaths were recorded in 30 countries. It spread panic worldwide. Global control of infectious diseases in the aftermath of SARS calls for prompt reporting, worldwide alert, rapid response, travel restrictions, research collaboration, upgrading disease prevention systems already in place, political and administrative commitment, community and media awareness and correct information management.

Injuries and non-communicable diseases also take their toll of human lives and, in many cases, induce disability. There are many hidden factors for communicable and non-communicable diseases. Abusive sexual practices, tobacco dependency, drug addiction, cardiovascular system failures, etc. are burdens of death to the community. Environmental pollution and health security is closely related. Pollution contaminates water, air and land. Toxic chemicals, radioactivity and ultraviolet radiation

⁴⁴Kaur, A. "Depression Emerging as Major Illness." *The Asian Age*, New Delhi. 8 October 2004, p. 10.

seriously affect human health. Health security becomes a costly affair. The studies of the UNEP and the WHO show alarming impact of environmental pollution on health security.⁴⁵ Instead of considering the impact on how many, it is better for health security experts to understand that the whole world is a victim of environmental degeneration and subsequent health hazards. There is no difference of opinion among health experts that the world is increasingly becoming a dangerous place to live in because of health hazards caused by unregulated modernisation and corresponding urbanisation. It is not a comfortable place for new generations of humans to enter.

Trafficking in drugs, spurious medicines and, of late, banned health drugs are increasing based on rising demand in spite of international restrictions. To that extent, it is a law enforcement problem. Transnational crime syndicates are involved in a big way in trafficking bodybuilding drugs. Trafficking in steroids has become a lucrative business.⁴⁶

Health security is at the heart of development. If that is so, it will be based on national development and will remain in contrast throughout since national development will not be in a global symmetrical pattern. Development of health security also means people are not becoming guinea pigs on health-related experiments. Notorious were the tests on American soldiers in the aftermath of the Second World War in the “land of giant mushrooms” where they were exposed to direct nuclear radiation.⁴⁷ Hitler too was paranoid. Many of his soldiers perished in unsuccessful nuclear experiments during the Second World War.

There are quite a few takes on matters of life expectancy (Box 19.3). Assuming life expectancy directly and indirectly points at general health and thereby security, then collectively one could see the general trend in world health as estimated by experts for various times and time spans span.

Box 19.3: Average Life Expectancy: Facts and Fallacies

- The average life expectancy of the world varied from a minimum of 54.36 at the Central African Republic to 85.29 at Hong Kong in 2020.⁴⁸
- Female life expectancy is more than male life expectancy in all the countries.⁴⁹
- Increase in national income doesn't guarantee increase in life expectancy.⁵⁰

Box 19.3 (continued)

- Average life expectancy is set to increase in many countries by 2030. It is expected to exceed 90 years in South Korea if a study has to be believed.⁵¹

There is also the other side of the story with respect to a country which is rich and affluent. The affluent need not be really healthy as one would expect in terms of affluence. The indication here is that optimisation of national security and thereby the NSI is not easy for any government unless drastic measures are taken to reengineer national security strategy that is being followed. The American syndrome is a random example (Box 19.4).

Box 19.4: The American Syndrome

The American syndrome in health security, according to this study, is the condition of declining health in spite of the country being rich and cares for the people by spending on matters of health and food compared to other countries. This is if the decline in life expectancy can be taken as a parameter.⁵² Will the interplay of health security and food security become the Achilles heel of the US national security because of its obsession with military security and economic security?

Americans suffer from high risk because of their habits of smoking, obesity, drug abuse, suicides, road accidents and infant deaths, poverty and less access to healthcare. Does this show health security has to be interactive with people? National security is a matter of governance and hence of governments where the government could be an individual to the entire people. In America it is the people; therefore, the people need to manage life expectancy too. The official governmental system can support healthcare.

The greatest challenge the world has encountered in the twenty-first century in matters of health security was the Covid-19 pandemic which did not spare any nation. Responsible governments showed considerable resilience and human concern since the virus has been identified in the Hubei province of China.⁵³

19.6 Caring for Health

There are quite a few findings and conclusions so far about health:

- Health holds the key to life in everything. Health is prim for human life.
- Health doesn't assure deathlessness, but a longer life span in the normal course sans unexpected disability.
- Death is not linked with health, but life span is.
- Economic affluence is not a direct sign of health.
- It is seen advancing time increases life span, but its link with health is not certain.
- Health seems to have links with human genome and human microbiome.
- Health to the people in a human system will depend on the quality of governance.
- Imbalanced focus on certain elements of national security can seriously impact on health security.
- Optimising elements in national security governance is a mandatory requirement for NS_{\max} with special emphasis on health security.

There can be more observations on health and human life. Interestingly the world need not be healthy even if life span increases. It cannot be. No better examples can be provided than the present situation (2020) when the world is reeling under the corona pandemic. The world has fallen sick physically, mentally and emotionally. The unhealthy state of the global humans is visible in the covid conundrum.

At the same time, it is an idealistic view to consider the world can be made or kept healthy. That is also not the objective of the principles of national security and the element of health security. According to the WHO, health is a state of complete physical, mental and social well-being.⁵⁴ Well-being is the key to national security. It is the goal. Maximising national security is the objective. In the definition of health, the quantum of well-being indicates the health of a society. The elements of national security will have maximisation of well-being as the end objective. The notion of health as an element of national security is a broad concept. It is not just the well-being of an individual patient on a hospital bed but the people of a country as a whole. A prospective patient, who everybody is, looks at the healthcare facilities before a judgment is made on the country's prospects towards a higher level of health security. The citizens expect to be in safe hands when they fall sick. The health security element is embedded in this belief system.

Ethics is an integral part of healthcare. Indoctrination of ethical practices is imbibed within the Hippocratic Oath that a medical student or a practitioner is familiar with. But how far the medical practices and ethics are involved in determining the health security of a community is debatable. Health security is more of governance than just managing the ailing. It is a much broader concept than sheer medical practice. Medical practice is aimed at treating a patient. Towards that the ethics hold acceptable profile. Once the goal of governance is understood, the ethics

⁵⁴Nussbaum, M. C., and Send, A. (eds.). (1999). Dan Brock. "Quality of Life Measures in Healthcare and Medical Ethics." In *The quality of life*. Oxford University Press. p. 95.

within this goal can be justified. Therefore, medical ethics does not contribute much to health security. It remains as a value system that may add to promoting health in a congenial way. There are also rules to take care of unethical practices. Again observance of such rules under the primacy of law is part of governance.

While the objectivity of medicine is to care for patient's health, the act of caring for health also needs to accept the limitations of providing health. Chronic illness by congenital problems or genetic disorder, injuries caused by accidents and disasters, trauma conditions, pandemics and epidemics, ageing, ill effects of medicines and treatments and many other factors contribute to natural limitations to health security. Providing well-being in health is more a psychological phenomenon than physiological. Health discipline in all walks of life can contribute quite earnestly towards health security.

Healthcare involves people; everyone is a prospective patient. Participation is important for effectiveness. Unlike in hospital administration where the doctor-patient interaction is a common activity of treatment, in a country, the government who is to provide healthcare needs to interact with the prospective patients—the people—for an educated decision on healthcare. In the former, it is medical care, whereas in the latter, it is healthcare, the subject of health security. Generally, all the decisions that are taken in dealing with health need not be contributory to health security. In health security, often, medical care is confused with healthcare.

Mortality rate is closely associated with objective assessment of health security though there is difference of opinion. Mortality rate of underdeveloped countries is higher than that of the developed countries. On the one hand, the argument is that the people in underdeveloped countries do not get enough life span for quality life. On the other hand, it also means philosophically, "What is it about life, anyway?" kind of syndrome if people die early since life itself is a grinding affair. The argument against is quite serious and scientific and underlies the importance of health in human life. A life that is lived full is said to have completed its biographical life—beginning, middle and end—in the fullest sense.⁵⁵ From the point of view of biographical life, a premature death is a life that is not lived full. There is a loss here in demographic security. It is a serious matter. In this attempt, health security is interconnected with demographic security. This cannot be said to infant mortality, which is a life extinguished at the beginning—before it started. It is a serious matter for a nation where the population is declining.

The United Nations has special concern in attempting to lower infant mortality rate. The rate of infant survival (RIS) is considered to be an indicator of the health state of a country.⁵⁶ Because such condition can be achieved only by good nutrition,

⁵⁵Nussbaum, M. C., and Send, A. (eds.). (1999). Dan Brock. "Quality of Life Measures in Healthcare and Medical Ethics." In *The quality of life*. Oxford University Press. p. 6.

⁵⁶Ibid. p. 339.

clean drinking water, hygienic environment and healthcare focused on antenatal care for women. This is also an indication of the physical well-being of the people of a nation. The RIS can be relied upon to assess this partial health security state in a country, and the planners may do well to understand it and the mathematics of improving it. Increasing the RIS is more of a political decision thereafter. One of the factors of the RIS is resource per capita. It calls for fairness in resource allocation. The success indicator for the WHO for infant mortality is less than 50 per 1000 of the population.⁵⁷

The world has serious concerns about women's health. There are 1,25,000 of women that die in India every year from causes related to pregnancy and childbirth according to government reports that called on people to help to break what it termed the intergenerational malnutrition cycle.⁵⁸ It is an admission of lower malnutrition level of the expecting mothers. The deaths are attributed mainly to anaemia, haemorrhage, sepsis and toxemia. The expectant women need nutritious extra food, regular medical check-ups and adequate rest.⁵⁹

Childbirth is a topic that is seen beyond the RIS in a society. It is an activity that has deep-rooted mental and emotional bearing. It is not just a mechanical act of physical disposition controlled by inbuilt instincts. Childbirth is different from other physical activities. The mental and emotional involvement is socially integrated in the community. The subject is beyond the normal applications of health security. That is where health security aspects may have to involve additional parameters to understand and care for health in a better way. In India, there are systems where delivery of a baby is in the presence of a woman member of the family. It is even official in certain parts of the country and found effective in providing moral, emotional and mental support not only to the woman but also to the child that is born in the course of time.⁶⁰ In traditional homes there were separate rooms for childbirth. A visit to one's own room of birth can regress a person back to the comfort of the womb in an emotional attachment to life itself. The comfort that the people are longing for in life is perhaps a return to the womb—to the care of the mother. Hypnotists, who suggestively regress their subjects to identify the flaws in their mindset to relieve them of built in inhibitions and negative conditionings of past life, noticed that a person found it most comfortable when regressed to the womb. That would have been the reason for people choosing the word "mother" as the most liked word in any language.⁶¹ Does this mean the quest of the humans for the

⁵⁷ Ibid, p. 352.

⁶¹ PTI News Scan, New Delhi. 24 November 2004.

ultimate security leads them to the womb? Well, certainly it is not the hospital ward where one would like to regress comfortably. It underlines the importance of families in healthcare for buttressing the mental and emotional aspects of health security.

For a nation, the cost of health security is the cost of total healthcare and loss of productivity by ill health. Health means physical, mental and emotional well-being in the element of health security. Currently, it is physical health that is the primary concern of the world bodies and national governments. Mental health takes a backseat; worse is the concern for emotional health,⁶² which is limited to off-the-track executive training programmes. Mental health is equally important to physical health since it is also subjected to vacillations in its realm. Mental health is necessary for harmonious working of the mind and is interrelated with physical health. Mental sickness affects not only the individual but also the family and society seriously. There is no universally accepted definition of what constitutes mental illness. Serious mental illnesses are schizophrenia, affective disorders, other psychoses, neuroses, organic brain syndrome, mental retardation, etc. A psychotic person has a deranged personality that is not in touch with reality. Compared, a neurotic is simple with mental disorders that are not attributable to organic cause. In a lighter vein, often it is said that while a neurotic builds a castle in the air and remain outside, the psychotic moves into it.

Surprisingly, empirical studies show that mental disorders are high in developing countries.⁶³ It is about one third among children. The aetiology of mental ill health is not well understood. Constitutional factors, physical factors, psychological factors and environmental factors are all included in it. Mental health problems can be of various types—psychosis, neurosis, particular disorders, behavioural problems, etc. Another variety is psychosomatic diseases comprising of organic illness in whose aetiology psychological factors play a key role.

Mental healthcare has taken a human turn only since the time of Philippe Pinel (1745–1826). The French physician, who taught mathematics and translated scientific and medical works to support himself for 16 years because of the restrictive regime in practising medicine in Paris, ultimately pioneered in the human treatment of the mentally ill.⁶⁴ Previously the patients were chained and treated like animals.⁶⁵ In 1792, Philippe Pinel became the chief physician at the Paris asylum for men, Bicêtre. There he took the bold move by unchaining mental patients. In 1794, he became the director of Salpêtrière. There he repeated it for the female patients. It was a social revolution in the treatment of the mentally ill. He also worked to dispel the

⁶² Arya Vaidyasala, Kottakkal. (2003). In the booklet *Jeevitacharya* in Malayalam, the WHO definition of health is mentioned as a state of complete physical, mental and social well-being and not merely the absence of disease or infirmity. p. 19. In this booklet published by one of the leading Ayurvedic research and treatment centres of India, the word “social health” is replaced with emotional health, considered to be wider in concept.

⁶⁵ Ibid. p. 421.

belief system that associated mental illness with demonical possession. Further to it, psychoanalysts like Sigmund Freud, Alfred Adler, Carl Jung, etc. brought substantial changes in the treatment of people who were mentally ill. Community psychiatry is a combination of the two.⁶⁶

Emotional health is the latest addition in place of social health as the third constituent of health security. It takes a person's emotional intelligence into consideration. The subject of emotional health has not gained attention of national security experts even as part of health security. It is considered to be individualistic in its application. Therefore, it is restricted to executive makeup for leadership skills. Emotional aspects of a society are very varied; it is where the landscapes of the mind change colours. Emotions cannot be said as positive or negative. It is a relative expression. Emotions are very much part of existence. All decisions, good or bad, are based on emotional backup. The society is governed by decisions under emotions. Therefore, it is for the governments to consider whether emotions have to be given a consideration in the overall national security make-up. The answer is "yes, and it is already late". The aspect of social health, which is already part of national security, if enlarged to the emotional scale, may do well in uplifting the emotional characters of the society through its members. This includes improving the individual factors of self-awareness, self-regulation, self-motivation, empathetic behaviour and social skills⁶⁷ of individuals and guiding them towards communal welfare in a group therapeutic mode. In the long run, this attempt will yield very positive results in harmonising many aspects of national security that will include demographic security, ethnic security, etc. Already the results are there to observe with respect to many nations where the people have asymmetrical attitudes based on emotional ups and downs.

The term emotional intelligence (Goleman 1995) is linked with the emotional health of people.⁶⁸ It is relevant to interactive environment. Including emotional balance in health security governance could be examined by governments.

19.7 Crimes and Health

It may be a topic that never gathered attention of experts in the field of health security, but ramifications of health crimes within and across borders have serious relevance in dealing with health security maximisation. There are international crimes now fashioned under a new terminology—transnational crimes. It is rooted in transnational corruption and exploitation. The idea has now gone a step ahead to call it

⁶⁶ Ibid.

⁶⁷ Goleman, D. "What Makes a Leader." *Harvard Business Review*. January 2004, p. 82. These five aspects of emotional intelligence were first brought out by Daniel Goleman as the signs of a leader. These aspects can be equally applied to a population for a healthy conflict-free communal life.

⁶⁸ Goleman, D. (1995). *Emotional intelligence: why it can matter more than IQ*. Bantam books.

transnational corruption and crimes (TNCC). These are major criminal operations that have national and international ramifications. Transnational crimes extend to health crimes too. One of the heinous crimes of this genre that affect health security is organ trafficking. Arrests are made daily, but the real syndicates that flourish internationally in organ trafficking do not get affected since the arrests amounts to temporary stoppage of traffic. Often the donors are aware that they are operated for organs for petty consideration. Some of their stories are very poignant. Besides losing their life-protecting organs, they also lose the money promised and future avenues for work since they become weak and emaciated for any useful job. Distressing are the stories that come from Africa and Latin America. In one such story, the police in Johannesburg and in Brazil arrested 14 people in a trans-Atlantic scheme to buy human organs from impoverished Brazilians for sale to desperate and ailing recipients in South African hospitals in August 2004. One of them was a recipient of a trafficked kidney. According to the Brazilian Police, the organ scheme was run by an Israeli syndicate, which was under investigation for a year.⁶⁹ Most of the organs being trafficked are the kidneys. The arrested were arraigned under the Human Tissue Act 65 of 1983 of South Africa, which bars sale of human organs.

The operators of the syndicate in organ trafficking canvass poor neighbourhoods in Brazil and other countries and find volunteers who agree to sell one of their kidneys. They are thereafter flown to the specified location or operated locally, and the organ is flown to the destination. A healthy kidney fetches up to US\$10,000. The transplant is charged up to US\$120,000.⁷⁰ Some of these transplants are made in prestigious hospitals. There is a worldwide demand for organs, mostly kidneys. The demand is increasing. It has become a flourishing underworld business. More than 80,000 people were waiting for kidney transplants (2004) in the United States alone. There are views in certain quarters that the restrictions on body part transfer should be eliminated on ethical grounds and that may also control exploitation of the poor.⁷¹

Another ghastly crime is human blood trafficking. This is mostly within a country. Victims are comparatively young. The police in Togo, South West Africa, had been able to identify the horrendous crime in blood and organ trafficking in certain regions. It is also an ethnic issue. It has been reported that most of them involved in blood trade belonged to the Igbo ethnic group of Nigerians settled in Togo. This is in addition to drug trafficking and petty crimes.⁷² Such trafficking was reported to be spreading all over southwest Africa and across Ghana. Many people were killed, most of them women.⁷³ In blood trafficking, the victims get killed, and

⁷³Ibid.

the blood is drained out in a hotel or other convenient place. The victims are obviously women and young girls who are comparatively helpless and have good healthy blood. The blood is drained through slit throats or cut veins. After draining the blood of victims, the perpetrators remove the reproductive organs. In Togo, many residents were annoyed with government apathy towards these killings. The Igbo's are generally considered to be committing the crime.⁷⁴ They are also suspected for serious crimes in Togo.

Murder to remove organs is common worldwide. Often people are murdered in the Mexican border to the United States especially in the border city of Ciudad Juarez and organs removed for transplant into the body of rich American patients.⁷⁵ Illegal organ transfer and trafficking are reported in Brazil. A voluntary organ seller from Brazil lost his kidney as well as the money he earned when it was pick-pocketed at the airport. He became an invalid and was back to brickwork, his old job. But this time he could not lift the same weight. And for him and others of the vanquished lot, life goes on faithfully detracted by destiny in valueless societies whining in the absence of positive governance.

Organ traffickers belong to a gruesome lot of criminals who often murder those who expose them. They haven't left even nuns who crossed their path innocently. A Brazilian was murdered for exposing human organ trafficking in Mozambique. A Sister of the Servants of Mary Immaculate was found strangled at her home in the northern city of Nampula in Mozambique.⁷⁶ The traffickers who were responsible for these gruesome murders were said to harvest sex organs from children to sell as charms for the practice of witchcraft in ceremonies to increase wealth or sexual vigour—all based on superstition. The people are angry in certain places in Africa that the authorities are helpless in controlling the crime. They know that the international ring of syndicates has established a violent cordon around the world and exploit or kill people to support organ trade, which is a highly lucrative transnational crime with heavy returns and limitations in legislative measures. Often people find bodies in the neighbourhood in African countries with eyes, heart and kidneys removed. There are also horrific tales from those who fled the crime scenes by providence. These reports coincide with the disappearance of a good number of children and young people either picked up while hitchhiking or kidnapped. In some countries, authorities are blamed to be party to it because of high-level corruption prevailing in the society at all levels of law enforcement and administration. The human charity organisations are also to blame. In one such case in India, an orphanage was allegedly involved in removing the cornea of an orphan girl.⁷⁷ This throws suspicion on the activities of adoption centres.⁷⁸

⁷⁸www.vachss.com. Accessed 26 August 2004.

International transplant mafia based in certain countries target the United States as the demand point for organs and smuggle people from poor countries on student or tourist visas. They, on landing on the United States, are whisked away from the airports to the hospitals. Their organs are removed thereafter and sold.⁷⁹ Mostly, the organs removed are the kidneys and lungs. There is a vast difference between the demand of life-saving organs and supply. The death rate in the United States in 2002 was about 17 per day for want of organs.⁸⁰ This is also an issue of concern for the immigration authorities.

Sale of human organs is illegal in most of the countries. Will legitimacy help people from dying waiting for organs? It is also an ethical question. While people are permitted to donate organs to family members on altruistic gesture, it is not so if one wants to sell it. The number of people waiting to receive organs is sobering. The number of organ donors is also low. This creates a separate world of cloak and dagger outlaw transplantation. Some operate under the loopholes in the system or take advantage of corruption within the system. That is why it is called transnational corruption and crimes in the new century. Illegal human organ trafficking is just one of the items in their agenda.

Another source for human organs is the terminal prisoners. In some countries, like China, organs of prisoners awaiting death penalty are available for transplant. Executed prisoners provide a rich source of supply.⁸¹ In China, execution of criminals is an organ festival time for those waiting for transplants. They travel long way to unhygienic hospitals waiting for someone to die in prison to give them hope of life. And, one day it happens. Prisoner organ harvest is denied by the countries officially where it is reported. Officials connected with the court sell the prisoner's body for huge sums after he is executed. Suspicion has arisen that the Chinese executions are part of a worldwide organ business.⁸² The patient pays the government-run hospital US\$10,000 for the service. Those who give more will be given priority.⁸³ Today, only the rich can afford organs from elsewhere. It is expensive. It can go up to US\$100,000 for an illegal kidney transplant in some cases.⁸⁴ In some other countries—Austria, Belgium and Spain among them—organs can be harvested from the deceased unless the individual has signed legal papers prohibiting it. This practice is considered to be of presumed consent. Most of the countries do not accept such consent. There is a need for an international understanding in this matter, and organ donation and sale could be made legal to save the needy. Notwithstanding the legal aspects and ethics, what is certain is that the shortage of organs will invite criminal activities within and across the borders of a

⁸³Williams, I. *The Observer*. 10 December 2000.

⁸⁴Ibid.

country. Organs of the poor will find a way to the rich through human conduits working under shadow. Overseas transplant agencies promise a heart for US \$240,000 and a kidney or a liver for US\$125,000 (2004). It is that simple. And it has to come from someone who is poor and will be poorly compensated for the role. The money goes to the traffickers. Of course, there is a caveat—there is no insurance cover.⁸⁵ Most of the operators spent jail terms in various countries. But they are back as soon as released. Money lures them, and it is plenty in this business of sleaze, corruption and murder. Yes, someone else gets a new lease of life somewhere. That is incidental to the operators. The fear of death, perhaps, is the ultimate key. Health security revolves around it.

There are also resistances in donating organs in some parts of the world. The resistances are far too many—cultural, ethical, legal, monitory and also compatibility even from a voluntary donor. All these contribute to the increase in crime with respect to demand. Health security is not to induce crime in providing health but assuring the health of the citizens of a country. The demand for body parts is increasing, and the current process based on altruistic principles is unable to meet the demand. The waiting time is very long and transplant is costly. Crime, therefore, is the natural visitor on scene to fill up the demand. The current system is evolved in 1960 and 1970 when the ethics of brain death and euthanasia were debated widely.⁸⁶ Buying and selling of organ was prohibited in the world in general. There are arguments in favour and against organ donation at a price. Why can't the people sell the body that belongs to them? Certainly there are not just physical disabilities but also emotional concerns about organ donation. Financial incentives may, to some extent, take care of emotional disturbances.

Mismanagement of medicines and medical applications cause health a serious issue in the hands of people who are not competent to do the job. The spread of HIV-AIDS was also attributed to surgical and syringe infections. Incompetent prescriptions, spurious medicines, side effects of incompatible medicines, unfounded use of alternate medicines, health tourism, etc. can be mentioned in this category. These are crimes, voluntary or non-voluntary. When not administered by qualified doctors, vaccines carry a high risk of infection from contaminated needles. According to a doctor *besides being unqualified, the administrators do not know the dosage, especially in case of children.*⁸⁷ Many are the opportunists in the field of health. Quacks and unethical medical suppliers and regular practitioners join together to reap it rich when health condition deteriorates in a country, and the government is in a hurry to contain the issue more on political reasons. Vaccination camps, house calls, selling of vaccines cheap, etc. will start immediately by the joint team only to make money more than a community service. Lack of awareness among people make them fall

prey to these ambushers of the psyche and not only administer spurious drugs but also administer them wrongly with infected needles, etc. The hepatitis and typhoid vaccines are mostly sold in this way in big cities.⁸⁸ Community health education is a way to get around these issues. Even in big cities, people fall prey to unscrupulous health practitioners.

19.8 Extraterrestrial Threats

A major section of the world community may not have taken it seriously, but there are scientists and policymakers who are apprehensive about the possible invasion of, if not already on, extraterrestrial pathogens imported unwittingly through scientific experiments. There may not be any defence for such pathogens, at least in the immediate future. Harmful pathogens from outer space could cause new varieties of pandemics. This is more probable in the human quest for finding life in distant planets and satellites. It does not mean that all life forms are human friendly and will come home to check out the evening programme on the cable followed by a joint meal. These bugs may make a meal out of their hosts. Most of the efforts planned in the world for the future are to do a biopsy of the distant object and bring that sample to Earth. It is a plan that may take some time. But astrobiologists should do better to understand about the visitors' compatibility with the earthlings. "You kiss me, I suck you in" bugs may even destroy the world out of its breath. Already there are earth watchers and astroscientist issuing warning on such missions. Is that enough? There are unconfirmed reports that AIDS and certain hideous microbes are the escapee fugitives from bioscientific experiments, which later multiplied outside the laboratory. It is important for the developed nations to understand that human search for the extraterrestrial life forms should not become the nemesis for the terrestrial life forms. It is chillingly practical. But the prophecies may be wrong. The scientists and policymakers are clear on the subject and have precautions lined up, though the experience of the world is otherwise in the past related to terrestrial pandemics.

19.9 Health and the Art of Dying

Health security means taking charge of life, starting with birth and ending in death. It is not just about medicines and physicians but the engagement of a government in the area of citizens concern for a welcomed birth, healthy—physically, mentally and emotionally—life and a dignified death. These three things, often, do not happen in a congruent manner to people of any country, as the studies reveal. The birth of a baby

⁸⁸Chatterjee, S. "Danger Lurks at the Point of a Needle." *Bombay Times, The Times of India*, Mumbai. 27 August 2004. p. 1.

may have some sign of welcome in certain cases, but is seen as a psychophysical liability in many parts of the world. Life itself is drudgery in an intricate socioeconomic system where the individual is precariously perched exploring the ways to manage it at all times. Finally, death is packed in the most undignified manner as a take away bonus to every human being without a choice of refusal. There is no good death. It could happen just about anywhere in a moment or after prolonged suffering—on the high planes of accidents, dingy chambers of the hospital beds, battlefields, sick rooms, isolated old age hiding places including one's own home without care... *Ars moriendi*, the art of dying, does not separate a human from another irrespective of the country or society he or she belongs. It is the penultimate decadence once born which gradually increases from birth. The only good thing that the dead feels about its post-death "life" is absence from the gruelling rituals and issues of bereavement. That is left to the not-yet-dead to go through. The society is still dirty and absolutely undeveloped as far as death is concerned and so are the governments who govern it. Governments have certain accountability under health security to ensure dignity in the death of the citizens. It is beyond and above ethics. That is when health security with respect to a citizen completes the act. Unfortunately, no government in the world, even the superstate, is concerned about it. Providing a death of dignity to its citizens is an obligation for the national security provider—the government. It has never been part of health security schemes. Every death is a painful affair not only to the dying but also to those associated with them—families and friends. A question that may come up in such system will be the oft-repeated mercy killing—is euthanasia acceptable to society? Euthanasia is the art of putting a person painlessly to death especially in the case of terminal or incurable disease (Box 19.5). If providing dignity in death to an individual is acceptable as a national security requirement in its element of health security, then euthanasia is very much a government responsibility and thereby ethical as well as legal. But in a world under the theory of invariance where changes take place at a pace that is virtually unnoticeable, quantum jumps are not expected in human governance. Euthanasia is riddled under law, corruption, crime and religion. Even then, death could be dignified under specialist medical practitioners (doctors of peaceful death),⁸⁹ hospitals designed as comfort resorts for the dying and adequate facilities for last rites and final disposal of one's life on Earth in every respect. The responsibility of the government in health security should end here, not short of it. It will be a revolution in national governance. The government has done its job in health security in relation to the dying if their souls on a revisit to the spot can return from where they came with fond memories of a beautiful death.

⁸⁹The title doctor of death was once given to Dr. Jack Kevorkian, who without serious concern for the laws of the nation, on humanitarian grounds as explained by him, had provided assistance to terminally ill patients in ending their lives peacefully. Euthanasia is also called assisted suicide and mercy killing. Serious debates are on the subject. The reference to doctors of death in this book is to doctors who are specialised in death-related matters who understand the dignity of death for individuals who are likely to die and provide comfort till death. This does not mean mercy killing. Mercy killing is not natural death.

Box 19.5: Homicide or Reverse Euthanasia?

In Tamil Nadu, India, there is a practice in certain traditional niches where relatives are “killed” by a practice called *thalalikoothal* when they become redundant under disability especially under old age. Senicide and involuntary euthanasia are other terms for this immorally cruel practice that also originates from abject helplessness or greed of others in the family. Some of them could be outright homicides in the name of the traditional practice for property and other benefit. The practice if viewed under the law is nothing but homicide. Various other practices where human lead humans to death such as a sati, cult suicide, abetted suicide, self-abetted suicide, foeticide, infanticide and so on exist within the human systems. Even the horsemen of apocalypse are there everywhere riding and striding silently looking for their victims among their own species.

There were two Tamil movies besides documentaries that portrayed the practice intensely.⁹⁰

19.10 Kill Bill⁹¹ and Other Ways of Dying

In the book of life, if there is one written by some form of life superior to humans, the food pyramid would not have been explained, unless humans were an edible, souvenir or some kind of other choice to them also. No one would have preached that every life form other than human is created for humans to eat and survive. Since this study doesn’t approve the statement “would or wouldn’t have been” as an introduction to a conversation or argument as life has only one-step change or alteration of course at any instant, mathematically, the question of a book of life anyway doesn’t appear in any argument.⁹² It also means that it is off beam to talk about a superior life form as there are no signs of it. Hence, as of now humans will continue to evolve and remain on top of the pyramid sensually and sentiently as a species. Therefore the nature and methods of killing are not related to life directly. It also cannot be related to human well-being. Hence it can remain as a human paradox of distorted survival mechanism.

The nature and methods of killing is not related to life directly that, if so, may be having corrective mechanisms within itself. This is evident from various dialogues in the context of life against killing and even negating capital punishments.

⁹⁰ Baaram (2018) and K.D engira Karuppu Durai (2020).

⁹¹ The term Kill Bill is taken from the titles of the American martial arts film and the sequel, written and directed by Quentin Tarantino that pitched well for any action movies. The volumes were brilliant attempts in movie making with many iconic and well written on the violent nature of individual humans.

⁹² The argument on “would have been” is based on the fact that in a one track choice, an alteration makes the extension of previous course in time null and void in a self-cancelling mode.

The other side of the argument is that humans are genetically predisposed to suicide and killing each other.⁹³ The basic static or dynamic territorial instinct, the prime reason of clashes, is visible everywhere in human interactions. Road rage is an example of dynamic territorial instinct. The aggressive and fiendish skirmish between the Chinese and Indian soldiers that killed many on both sides at the border at Galawan on 15 June 2020 with nailed sticks like primitives was an example in static epithet.⁹⁴ The interesting part of such aggressiveness of humans against humans is that they can be rationalised for justification. Human conflicts and survival emotions such as anger, hate, rage, wrath, jealousy, envy, vengeance, etc. are indicators of the preoccupied destructive psychology in humans. Today humans are at the top of the kill-directly species. But that is not the only way humans get killed.

Humans kill themselves and get killed either by other humans or life forms or for various other reasons even before they clock the time allowed genetically by birth. In fact, they leave before the visa expires. People get killed directly, indirectly and vectorially through agents such as mosquitoes (surprisingly the number one killer according to one study). A random data of animals that kill humans including humans gathered from various open sources is presented in Table 19.2 for information. The numbers are avoided being irrelevant with this study.

⁹³Fields, R.D. (2016). “Humans Are Genetically Predisposed to Kill Each Other.” <https://www.psychologytoday.com/us/blog/the-new-brain/201610/humans-are-genetically-predisposed-kill-each-other>. Accessed 23 November 2019.

⁹⁴Panda, A. “Skirmish in Galawan Valley: India and Chin’s Deadliest Clash in More than 50 Years.” TheDiplomat.com. Accessed 13 December 2020.

Mossies top the list, killing around a million people every year. In contrast the humans stand second with almost half the numbers. Humans could become the ultimate Kill Bills in the future. It also means the governments may have to appreciate it while strategising national security with respect to the rule of law and health security.

19.11 So, What Is Health Security?

Health security, in this study, is the 11th identified element of national security in the chronological hierarchy of 16 elements. Health security, “healthsec” in short, with the symbol “ h_s ”, is about maintaining the health of the people of a country at any given time by preventing, preempting and administering health insecurity issues, for the overall maximisation of national security.

Health is the primary factor of a successful life in a human system and covers the aspects of physical, mental and (or including) emotional health conditions. The health of the citizens, though correlated with many factors such as nutrition; genetic and biomic inputs; living environment and others, is a factor that indicates the quality of governance in a human system. Health security also includes the comfort in disability and death which is inevitable.

Health security is not about preventing death. It accepts it by separating health from death. It is about providing life to humans till they die including caring for them until they die naturally. Euthanasia is one way of helping an individual die, but it is left to the government to take a call on it from the point of rule of law. This is also similar to social euthanasia (which is termed as involuntary in certain quarters though remains an issue of ethics and values of the prevailing social belief system) and when they are going to die inevitably.

Humans get killed directly or indirectly through various life forms including humans that act as vectors. It could be anybody including a pharmaceutical company that has slipped from the expected normal.

19.11.1 Definition: Health Security

Against the background of this study, health security means the capability of the nation to protect and maintain the physical and mental including the emotional health of its people and mitigate the effects of public health incidents that endanger the collective health of the people and provide support to global health through responsible and ethical international cooperative engagements, *perfectly aligned with the other elements of national security and integrated with all the terrains of national governance.*

19.12 Summation

Health security calls for concern of governments for the people that starts at the time of conception of a life till it ends. It calls for efforts on the part of governments and people to make the passage of each life from birth to death beautiful, comfortable and dignified. It is not a random wish. It is very practical under the principle of national security. That is the whole aim of the element of health security. Not only the process of dying but also the life itself needs to be demystified for this objective. There is a general feeling in governments, and also those who govern, that health security is related to medicines and diseases. In this chapter, it has been explained that it is a holistic topic that covers everything about life—birth and death included. Health means the physical, mental and emotional aspects of the individual human and the group collectively. Governments do not see these aspects, especially the mental and emotional health of the people, seriously, when reference to health security is made. It is required to be incorporated in public health management. A nation cannot be balanced unless its collective psychological (mental and emotional) mindset is not stable especially when the world is advancing. The slip will show in the overall national security. Considering that emotional intelligence is a relatively modern finding and nations are slowly gaining awareness in psychological matters, it is expected that, in the course of time, there will be certain relevance to these aspects in the overall health security management.

Today, the WHO is the health keeper of the world. It is good news because health security is part of global security and can be achieved only at the macro level more effectively. The WHO's success story is the eradication of small pox. Up to the late 1960s, the combined total of some 15 million cases of small pox occurred annually in 33 countries. The WHO waged a war against small pox in 1956. The last case was reported in Somalia in 1977.⁹⁵ The virus is still kept in secure laboratories in the United States and Russia though there were calls for their destruction.⁹⁶ Monitoring, immunisation, survey and containment are the factors that any health security management scheme has to envisage in providing total health security.

In health security, people put all restrictions away. People may do anything for health and escape death. When the clock ticks loud in life, vegetarians may eat meat, non-vegetarians may chew on horseradish, fanatic may change faith, busy executive may idle in yogic slumber, anti-abortion campaigners will go in search of human foetuses for a cell shot, millionaire playboy will immerse in the chanting of the guru of the of the art of dying variety, rational will become superstitious and dance with dry human genitals around the neck for a cure for the tiny lump inside the brain, and the terminally ill will plead for death that they feared once. That is what life is about. There is nothing more fragile than life, not even a soap bubble. Health security means making it float comfortably within this fragility.

20.1 Introduction

Sans the singularity aspect, every sapien is not only different from another but also (differently interact) with self as personality changes. The difference between two people is much beyond the belief systems and sociocultural departures. A person thus becomes a perfect human islet of reason projecting differential biosymptoms at any given time. It is applicable to everybody—from the ordinary to the exceptional in social or self-perceived hierarchy or social pyramid. Nothing prevents a sapien to think singularly (similar to everyone) at one moment and differently (absolutely different from the other even in a common scenario) at another though both ways of thinking is original and common to all. The latter creates a divide sometimes poles apart in dealing with another. That, under the principle and choice of national

security elements, induces the typical behaviour pattern, called ethnicity in this study, much beyond the definition of the same term in today's lexicons, media, political talk, university studies and whatsoever dialogues and expressions in human relations. Everyone considers everyone inferior to everyone where the "everyone" is self. That is what a government has to bust. This study calls it ethnic security.

The ethnicity in national security governance has nothing to do with the words such as secularism, equality and so on. It is simply about differences between people that cause issues in national security governance. The governments will have to steer within ethnicity of all kinds nationally and internationally. It's not a serious problem. There are many inbuilt balancing forces within the ethnicity demarcation that the governments can make use of. Besides, the government has the power that can be used sans abuse.

Human beings carry simmering volcanoes buried deep inside their mindscapes ready to erupt without warning causing incalculable damage to them and those around. The unseen landscape of human emotion is more varied than any passage-way or terrain on Earth. The mental landscapes force humans to be islands in isolation when dormant ironically within a cluster. The human islands are so fragile that they can be wiped out in seconds by a turn of fate.¹

A nation comprises a multitude of people who do not share a common narrative or even speak a common language, forget the accent, in most of the cases. But a nation is a system within a boundary—the largest human system.² What they may have in common will be a nationalistic background with the culture of a nation superimposed on it, like the statement the *great American dream*; what the Indonesians say, *Bhinneka Tunggal Ika*³—unity in diversity; or the way the Indians sing about their country, *Saare jahan se acha*,⁴ better than all other places (in the world). They firm up the system boundary perceptively. But for a few select catchphrases, no one shares anything in common in a population where gender, age, education, health, occupation, status, religion, race, caste, tribe, culture, colour, creed, belief

¹Fate in this study is a chance-induced event—an upshot when the cause is difficult to explain. For chance see Chap. 4.

²A system will have a boundary. A nation is the largest human system within an appreciated system boundary. Global human system doesn't have a system boundary for governance as a whole. It is not yet a system but called as system sans boundary. The smallest human group with a firm boundary is the family.

³From *Kakawin Sutasoma*, originally written by Mpu Tantular in Old Javanese language in the fourteenth century, literally meaning "(Although) in pieces, yet one". It is usually translated as unity in diversity.

⁴From the ghazal style patriotic poem *Tarana-e-Hind* (anthem o Hindustan) written by Muhammad Iqbal in Urdu (Ittihad, Weekly, 16 August 1904) as an Indian nationalist. Later he turned to be an Islamic fundamentalist (Islam first) and wrote an Islamic supremacist anthem *Tarana-e-Milli* (anthem of the religious community) (1910). Iqbal was the descendent of a Kashmiri Brahman (pandit) whose family converted into Islam several generations earlier. The ethnicity and change are vibrant in a single life. It is not an irony that Iqbal became Pakistan's national poet according to this study. It is an interesting example of how ethnicity changes and people's view are altered within human systems.

systems, politics, location, money, situation, sexitude, nature of job (government and non-government) and other agents of division play truant with each other. All these and any other separating identities that differentiate a human from another, in whatever form it may be, in individual and social perception are brought under a single term in this study—ethnicity. In spite of these differences, ethnicity generates a human system where everybody is right. This fact brings the humans closest to animal life. In the animal world, every animal behaves as if it is right in everything it does by survival instincts. Irrespective of what they are, every human being is required to be protected from threats to national security that include threats from each other. The role of the government in national security is to bring this awareness among people and protect them till such time they are capable of protecting each other, recognising human rights of equality and equity in an emotionally healthy society. The element of ethnic security will then be a thing of the past in national security. And that, if the past is to be believed, is not going to happen. For this reason alone, the concept of ethnic security qualifies to be an element of national security. The government has to ensure it.

Ethnicity, however, though aimed at individuals, does not see humans as individuals. It views humans as groups that share common and distinctive characteristic traits. That is another find of the concept. Ethnicity is caused by well-conditioned individual behaviour traits. Its effects are seen in the individual as a member of a group. This characteristic of group identity can be based on any of the dividing factors—racial, religious, national, linguistic, cultural, heritage, occupation, etc. This solidarity under an ethnic makeup is for reasons of individual isolation explained before. Without ethnic bonding, individual isolation becomes unbearable and can destabilise the personality of an individual. Therefore, ethnic bonding of some sort is an accepted reality in a society. From the national security point of view, the ethnic bonding is not restricted to the few factors of religion, culture or language alone, but all those that contribute to a difference within the human system between one and the other. Such endeavours direct the humans to identify common characteristics between them and others and bond with each other to protect from drifting into isolation. The individual sets aside differences during the attempt of ethnic bonding or ethnic cohesion. Anything matters here. Such bonding once it happens will make others with dissimilar bonding as ethnic aliens within their own society or national boundaries. Ethnic security, in this sense, means the security that is required for harmonious living of more than one group in a nation. The easiest way to bring in ethnic security is by inducing or flaming cohesive feelings. This, perhaps, may be a bit out of place in the world of the future for reasons that are beyond this chapter. For a government it remains a matter of governance towards maximisation of national security— NS_{\max} .

While ethnicity is propagated by the built-in insecurity in an individual, the evil within is rooted in discrimination. Perceived or real discrimination leads way to belief systems of which the most dangerous part is nihilism combined with ethno-neurosis. Under such circumstances, an individual feels at the highest level of ethnic insecurity, “my culture can lick yours” or “my god can incinerate yours”, which is the feeling that ends up in pronouncements for action. The psyche of the converts is

often imbibed with such feelings especially when insecurity is the governing emotion. It will be interesting to note that most of the fanatic haters had their own elders in their genealogy belonging to those whom they hate. Muhammad Iqbal (1877–1938) who wrote a prestigious anthem for India is remembered as a hero in Pakistan as its national poet. He said to have hated India since 1905, favouring Islam. The ex-premier of Pakistan, Zulfikar Ali Bhutto's (1928–1979) family belonged to Hindu Rajput clan. His mother Lakhi Bain was a Hindu who converted into Islam⁵ before her marriage as Khursheed Begum (dates unknown). Giasuddin Tughlak's (not known–1325) mother was a Hindu.⁶ By repeating these backgrounds, carrying candles to the Indo-Pak border or a cross border *samjhauta*⁷ express train may not alleviate the problems of ethnic security. Powerful and determined force bred in insecurity and hate may control and contain ethnic differences to a large extent. Every nation has ethnic problems. Human understanding dissolves in the dilution of identity. Farcical vibes of ethnic insecurity resonates all over the human system. From the point of view of national security, ethnicity is not limited to select cultural and religious diversities. As mentioned earlier, it is a much wider terminology that includes the entire continuum of humans—divided and isolated in togetherness.

20.2 Ethnic Security—Setting

Ethnic security is about governing the well-being of the people of a nation, by the government, by treating them equal without bias to ethnicity of any kind. This is normally part of the constitution, or should be. But it may take an inadvertent shape in the constitution while drafting it. For the purpose of national security, ethnic security covers all the aspects of differences in human attributes, not behaviour, and corresponding comparison. There are many factors that separate a person from another “ethnically” according to the term used in this study.⁸ It covers every characteristic that differentiates one from another. The differentialities are not based on taxonomy or biological or any other similar classification, but “human belief systems” as perceived and decided based on power gain under the thriving feeling of permanent or temporary insecurity. The statements are based on this study and author's viewpoints from the accepted normals. There can be differences from the common ideological perceptions.

⁵Many Hindus were said to be converted into the religion of Islam in India by force or otherwise especially in the seventeenth century during the Mughal Emperor Aurangzeb's regime. The first member of Bhutto family “Sheto” allegedly converted for tax exemption for Muslims.

⁶Balbir K. Punj. “There was Life Before Islam.” *The Asian Age*, New Delhi. 21 January 2003. p. 16.

⁷Hindi word for mutual understanding.

⁸Ethnicity or ethnic character by one of the dictionary meanings covers sizeable groups of people sharing a common and distinctive racial, national, religious, linguistic or cultural heritage. In this study it means any distinguishable character that differentiate him or her relative to another as individual or belonging to a group.

In this gobble-de-gook of human mindset, insecurity is a great gamer. Insecurity is the key driving force behind human survival and existence. To that extent it is not a negative aspect or characteristic but a built in necessity. Ethnicity has insecurity embedded in it. It also means ethnicity is a natural separator that will stay. But for the governments, it should be for consideration as a natural occurrence in a human system which they may accept and find solutions to balance.

An interesting and appreciative example of the prevalence of ethnicity and also a case study in governance of ethnic security in modern times was set by the American government. According to the news an African-American, named George Perry Floyd (46) died after a white police officer, Derek Chauvin, pinned him to the ground and knelt on his neck after handcuffing him. “Despite Floyd saying, ‘I can’t breathe’, the policeman did not budge, while the three others standing near him looked on”; it was reported.⁹ It happened on 25 May 2020. Official post-mortem declared the incident a homicide.¹⁰ Police officers reportedly use the controversial knee-to-neck move while making an arrest, which they can argue for self-defence. The death of the “Black citizen” with the involvement of a “White citizen” (such statements are shadowed by ethnic differentiation and used for academic purpose only and also to show such things do happen all over the human system in a million plus shades other than the usage of terms such as black and white) caused all-around protest in the United States, attacking police brutality and racism. There was rioting, tear gas, baton charge, looting and walk the bunker or panic room for the president for protection—signs of bad governance of ethnic security. All these happened when the country was reeling under the Covid-19 pressure. But the subsequent signs showed how the government brought back the situation in the middle of the protests. In an admirable attempt, several police personnel sans any sign of ethnic differences reportedly apologised for what the rioters accused them—the police brutality. Several police forces expressed their solidarity with those speaking out against police brutality and racism. They laid down their shields and helmets and knelt before the demonstrators hanging their heads pensively to extend their apology for killing Floyd by bending him.¹¹ They asked for the Black community to pardon them. It moved the people to the verge of tears and was very humane. It also shows the social evolution where humans are becoming more emotionally considerate of fellow humans which would not have happened a century ago.¹² But there is a long way to go for the sapiens for removing ethnic security from the list of national

¹²The trend in human concern for suffering fellow humans were seen since the days of Charles Dickens (1812–1870) who wrote about it in his literary classic novels.

security elements and becoming sapien humans.¹³ In this model of ethnic security, the players (White cops representing the government) and the victims (Black cop) merged in support to the people without ethnic duality. The American model magnanimously demonstrated by the police, genuflecting as an apology accepting the folly on duty, is the way national governance is trending. From the point of view of humanism, it would be more appropriate for governments to consider interventions that do not have to follow submissions post incident. It may take a long time as evolution has to catch up with ethnicity. The problem with ethnicity is that it is not a matter of morality but survival. It needs tremendous power of advanced intellect to overlook differences and live under singularity of purpose for humans. That is the reason ethnic security has to be seen in every aspect of human difference which never acts alone. Hence ethnicity is a multitudinous sapien characteristic. The government can act on it. That's good news. The governments can also initiate ethnic conflicts instead of resolving them. That will be bad news.

Ethnic specificity in the study of ethnic security can be easily misread. The macro ethnic details are examined further as they are important for governments to function positively. The way they are explained here are for this purpose—governance, only.

20.2.1 Examining Macro Ethnicity

Having said ethnicity is about all kinds of differences between a human and another, at a specific time, consciously and subconsciously projected in interactions between humans and human systems, it may be understood that it is the constitution of a country that decides the expected ethnic behaviour for the purpose of governance. However, for behavioural aspects of individual and group human, it may be based on the conditioned behaviour, ethics and value systems and behavioural etiquette and protocol that one has to follow at the highest level of social order even ahead of the period.

This statement advocates that the prime behaviour expected from a person in relation to a fellow human should be what is expected to follow at least one life time ahead of that individual. It is the opinion of the author in the positive belief that evolutionary aspects of humans slowly erode ethnic prejudice in regular life. Humans can become more conscious and responsive. The author calls it “forward ethnicity” for following in the present for a social system sans ethnicity other than acceptable differences. It is an ideal situation and for the purpose of decisions on the ethnic factor of an individual human or human system. Opposite is “reverse

¹³This incident can also cross over to informational security, and the entire episode can take a different turn in decision-making in governance if the accused (Chauvin) and the victim (Floyd) were known to each other and had any personal contact before the incident. The assumption here is that they both were total strangers. The ethnic security deficit doesn't apply to the incident if they had any previous relations. The author has not researched this part. Ethnic security has to be seen in perfect informational conditions and not based on casual conclusions.

ethnicity”¹⁴. These terms are further explained in the chapter. Normally there is an evolutionary time delay in ethnic behaviour among humans that degenerate into irreversible deep time period. Most of the ethnic behaviour patterns are much older than the acceptable normals of the present even at the most advanced end. The readers may recall the idea of unitary civilisation and the worm tunnel with the most advanced at the head and the least at the tail end.

Macro ethnicity matters seriously in governance. It is a cauldron of violence that can bring severe grief and trauma to people if kept open. Nations can split and micronise under macro ethnic differences. Macro ethnicity is about the concerns that a government will have to deal with for meeting the constitutional requirements in governance. They are many. Some of the common differentialities at the macro level are briefly examined in the succeeding sub-subsections. They are examined at random sorting based on author’s choice for explaining briefly as it is the viewpoint exclusively for this study. Any difference of opinion is very well accepted as peoples view can be different. This study respects every view from the point of fundamental freedom of a human by birth. Ethnic separatives are very powerful; therefore it is important for the government to know them for governance. The interesting aspect is that the same forces can be used to harmoniously join people.

Macro ethnicity is briefly examined through the following ethnic differentiations in vogue.

1. Culture
2. Religion
3. Race
4. Caste
5. Tribe
6. Sect
7. Politics
8. Language
9. Nativity
10. Lineage
11. Age
12. Gender
13. Sexitude
14. Education
15. Money and wealth
16. Status and position
17. Role
18. Deceased
19. Occupation
20. Others

¹⁴Forward ethnicity and reverse ethnicity decide the human movements and their positions in the worm tunnel of unitary civilisation.

20.2.1.1 Culture

Culture conjoins people more than it separates. The author is sure about the power of culture to gravitate people to each other. This is an interesting aspect in governing ethnic security. Differences can also unite. The term “soft power” is brought in to underscore the power of culture, though using the term relative to hard power is not author’s choice. They are different. Soft power is not power the way it is necessary to dominate. Culture is also more original than other ethnic separatives. Because of its ability to connect people, culture is more important for governance than the other differentials in governing ethnic security. It can be used by responsible and intelligent governance to ward off the negativism associated with ethnic differences. Yes, culture also creates separation and girth which sometimes can go very deep.

Culture too carries many definitions. One of the dictionary meanings of culture is “the behaviour patterns, arts, beliefs, institutions and all other products of human work and thought especially as expressed in a particular community or period”. In another meaning, culture is “the arts and other manifestations of human intellectual achievement regarded collectively”. Also it is “the ideas, customs and social behaviour of a particular people or society”. Another definition is that “culture is an umbrella term which encompasses the social behaviour and norms found in human societies, as well as the knowledge, beliefs, arts, laws, customs, capabilities and habits of the individuals in these groups”. Yes, all are acceptable. But in the practical game of governance, culture (and other terms) needs to be defined for pragmatic assimilation.

All these show basically culture is the base that cues in and stimulates the behaviour pattern in an individual and accordingly shapes and modifies his or her personality from childhood. The behaviour forms the crux of acceptance in the identified cultural society. It becomes the way of life. This can be seen in linking the term “way of life” with culture. Culture is defined from this perspective as the “way of life” of groups of people, meaning the way they do things trending the taste in various behavioural patterns and activities including fine arts and humanities, reasoning, knowledge, belief, outlook, attitudes, values, morals, goals, customs and responsive behaviour in a society. This way culture can be defined for this study as “the acceptable behaviour pattern of an individual or a group within a defined human system contributing to an ongoing way of life that is changing slowly but unseen and unfelt at a given time under the law of invariance without deviation from acceptability”. Culture, therefore, belongs to a human system that is intrinsically part of it. The culture turns to a religion which in turn may contribute to become a differential culture or continue as before in the format of a cultural religion as demography changes with the birth and death of people within it. The cultures thus formed become ethnically different from each other unless seen as a religion in which case the religious perception becomes the differential factor sans the culture. There is nothing special about it except in matters of governance. A country is a total human system. It will comprise many cultural or religious (religion too is culture) separations that the government will have to govern. A national security

index too will not serve the purpose of appreciating a government's capability vis-à-vis another unless the term ethnic security is seen as a common denominator the world over with striking difference between the countries and within the countries themselves. Yes, complicated but not that difficult to govern under the authority a responsible state has. A state is more powerful than its people.

20.2.1.2 Religion

Everybody understands religion, but no one will be able to define it for universal acceptance. This study too faces the dilemma. That makes the first part of the sentence that “everybody understands” untrue. If understood universally, a unified definition is not a far cry. Religion is the much talked about ethnic difference in a human system. In the process of its evolution, “religion” created a negative sense of separatism and insecurity¹⁵ and invoked the feeling of hate among people from the beginning, though every religion claims to preach “peace”,¹⁶ some within and some around through the so-called sacred books. They are sacred though, being supreme in considered behaviour. Today religion is associated with intolerance and killing among majority of humans if not all. It shouldn't have been being sacred. Simply put it is the challenge that “my god can lick yours” kind that religions give to each other in spite of the argument god is one for all as a belief system. Sadly some religions subliminally preach to hunt and dislodge the other by any means—conversion, coercion, apathy, domination or death.

The entire scenario is incongruous and sardonic because the need for religion is only for humans to balance their mental stasis under emotional discomfiture. An ape or a bacterium doesn't follow any religious preference. Humans took to religion as they found it helps to manage their emotional health and control sparkling anxiety without breaking the bottle. God exists even in a non-existent form for some and is necessary for humans driven by highly sensitive intellect to survive. But the ethnicity of religion drives a wedge in the process. If that can be governed, religion will serve the purpose.¹⁷ People may agree. One of the author's students, Muhammad Aslam, answered a query on the need for religion in a discussion saying: “Religion keeps

¹⁵This separatism and insecurity are common to all ethnic differences but are governable. That is why ethnic security is considered an element of national security after testing under the qualifying condition of governability. It is governable under a constitution though it goes as per the will of the majority.

¹⁶It is one of the reasons why this study seriously advocates peace as an abstraction that is neither unreal nor real.

¹⁷There are governments that run religion. It is not the job of the governments. Governments are not supposed to be religious. Religion falls under perceived security. Governments are meant to handle apparent security aspects and people; especially individual humans may handle perceived security aspects. Government appointed devaswom boards that control Hindu temples in Kerala, India, and similar others that control perceived security directly through governments, therefore, can be counterproductive in national security governance. Governments may see the incomes under special governing principles.

humans disciplined; it prevents criminal activities". For Another student, Aishwarya Rameshan, religion offered "peace of mind". Both were balanced and acceptable answers. (After all they were author's adorable students.) But, as already mentioned, it was also the problem with the students to define religion. Scholars, practitioners and followers have been experiencing this problem for years.

Religion is defined in many different ways. Multitudinous definitions of an entity project the idea that it is abstractionist though practiced by humans for a "purpose" or "reason" that they would have considered necessary. The definitions are quite controversial where people disagree seriously, sometimes even conflictingly. There is no universal definition for religion as in the case of any abstraction. The author's little girl, the 7-year-old granddaughter, Ishika, had a question (2020). When she called him long distance for a delectable kiddish chatter that he always waits for, asking to see her art work, he busily told her that he was in his study writing.

"What you writing, Nanu (grandad)?" she asked.

"About religion" he said.

"What's religion?"

"Well, err, it is something, hmmm, you see. . . It is about god".

"Oh, you don't know nanu?" She knew that her nanu was dumb and confused.

She, perhaps, meant to ask how the author could write about religion when he himself was not sure about it. That is the catch (Caveat 22)¹⁸ here. Presently readers and listeners have no other option but to bear with such abstractions of verity for some more generations to come on many matters that breed ethnicity, besides religion.

Commonly in the belief system based on the acquired and conditioned culture, a human holds "faith" in gods, unitary god or no-god, where "no-god" is god in this study specifically under the "god-is-personal" argument.¹⁹ God, including gods and no-god, is the key point in religion. Belief in no-god if it is strong serves the same purpose as belief in god or gods. Religion cannot exist unless there is god and is one of the supporting arguments. This can be modified to say any belief system single pointed on identity and security is religion. That makes a political system a kind of religion. The leader, the most powerful within the political party, becomes god, and those who have intermediary access to him or her become gods. Here a political party or any system of power becomes a biomodel for religion under similarities, regimented and focused among other differences.²⁰ But the discussion is about religion in the natal form with prenatal antecedents.

¹⁸ Caveat 22 is used as a catch phrase where the caveat originates from catch 22 popularised by author Joseph Heller (1923–1999) in his book *Catch-22*.

¹⁹ In Hindu scriptures, God is unitary and SELF; that means God is in everyone; everyone is God, but everyone is different from each other. It becomes an abstraction with an in-depth meaning based on the period. See *Bhagavad Gita*.

²⁰ The argument "no-god" is also god applies to political system that doesn't approve the existence of God. That's why any political system could be biomodel for a religion.

From religion, if god including no-god or gods is taken off, one gets culture, but it is not possible. A culture cannot stand alone under extreme insecurity that humans face and cannot handle alone. But a culture can be turned or processed into a religion simply by adding god. That's what happened originally and thus the name original people for the followers before specific cultural religions appeared in one form or another under strict regimentation as religious cultures.

The key difference is whether the culture precedes religion or religion precedes culture. Culture can precede religion or religion can precede culture as on the present day evolutionary stasis of human intellect. Every human is part of one or more religions. In the course of time, it could be hypothetically assessed that every person will belong to a multitude of religions. This will dilute the unitary and original religion until uniformity is achieved in differentiability among humans.

This hypothesis is put forward based on the main difference in the duality of religious beliefs. The difference originates from the cultural aspect of religion. Religion separates people into the duality of groups with each group having its own subgroups and sub-subgroups that could go on infinitely like in a hall of facing mirrors. It is also one of the ways religions will get diluted to null as evolution progresses through knowledge. So the religions according to this argument can be classified into two types in relation to culture:

1. Originated from culture. They can be called cultural religions. They are culturally processed belief systems that lead to perceived security as an act of mental balancing. The original people are born into a cultural religion and may either continue or get processed into a religious culture. The people who follow cultural religions acquire religious beliefs prompted by the culture.
2. Transformed to culture. This study calls them religious cultures. They comprise people who are born into a cultural religion originally and then transformed to another religious belief system which subsequently acquires its own culture as religious culture. Subsequent generations of people continue in the religious cultures. The people who follow religious cultures acquire cultural beliefs prompted by the religion.

In the language of the author's friend at the immigration counter at an international airport, there is no difference between the two types of religions except from the stance from where the observer views them. What has immigration got to do with religion (Box 20.1)?

Box 20.1: Cultural Religion and Religious Culture: The Two Sides of the Human Belief System

Both show culture and insecurity and are closely intermixed. Culture in a religious format, whatever it may be, is necessary for humans to balance. It is similar to emigration and immigration—both are the same. Emigration is “leaving from”, and immigration is “entering in”—both in one go of

(continued)

Box 20.1 (continued)

migration. This argument is meant for the government to understand governance of ethnicity of culture, and religion or any other ethnic difference should be comparatively easy if it is not stoked with vested interests. There lies the catch.

This was the way for humans since the beginning based on inherent fear default cuing the feeling of insecurity in the mortal world. They began seeking the intervention of superior forces in natural forms as perceived by them under fear and feeling of insecurity. The evolutionary progress in human development turned people thereafter to move on to unified god system or no-god system for preferred way of living as the existential thought processes progressed and demographic density increased. They hoped to become collective in belief systems without knowing humans are interactive species by origin. But the forces of insecurity are extremely strong and haunting. People, thus transformed by culture under refreshed belief systems, became culturally religious people. Under this argument, originally, there were only culturally religious people in the world. Figure 20.1 describes this process. The gap is an unknown factor in the future. It cannot be predicted even intuitively (law of limitations) how the turn of events will be. But it is almost clear to this study that a person from the processed religious culture cannot be recycled to the cultural religion except for sociopolitical purposes as it will miss the most important element of behavioural system—early conditioning. And also there is a supplementary finding to it: There cannot be any more cultural religions in the world in future.

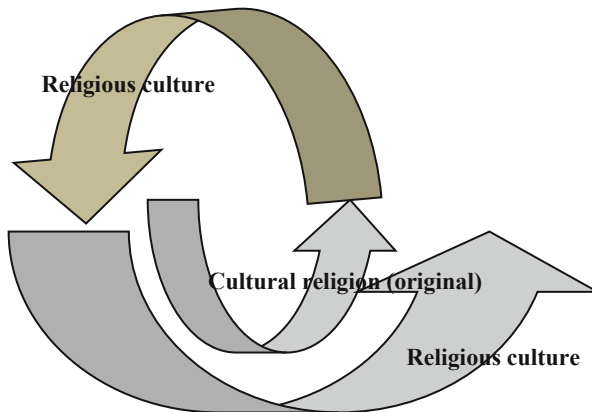

Fig. 20.1 Cultural religion (original people) interfaced with religious culture the regimented religion

Note: There is a point of separation between a religious culture and a cultural religion as the religious culture cannot be brought back to cultural religion in terms of conditioned belief system, but it is possible for a changeover from one religious culture to another religious culture. These statements are hypothetical as they are heavily influenced by conditioned belief systems

Though the original people (the cultural religious people) can be transformed or processed into religious cultural people, there are problems for the reversal of the latter unless for sociopolitical reasons from religious culture to cultural religion.

20.2.1.3 Race

Race is more an ethnic slang than actual colouration of human behavioural differentiability. Simply put, race, as an ethnic difference, should not have been there in the long list of ethnic typology of human separation since it is a false positive according to the author. Race is also a relatively fast-waning theme of ethnicity as the world and simultaneous human concerns advance. Humans were differentiated based on human divisions in the form of race: Australoid, Caucasoid, Mongoloid and Negroid as divisions in biological taxon as early as 1780. The older concept was five races—African, Asian, European, Native American and Oceanian. This classification of races was based on inherited physical differences—birds of dissimilar feathers, but still birds.

These divisions became the origin of racial ethnicity but are outdated today. Later on human divisions by race turned out to skin colouration. Race is universally practised and criticised at the same time. It can be said that race as a theme of human separation will be the first parameter that will lap dissolve with time followed by other types of differentialities that may last much longer. This is a hypothesis generated, observing the trend around the world where awareness about race and racial discrimination is gaining momentum. This could also be used as a supporting factor in the hypothesis that race is a nonexistent factor of separation. Race, therefore, is a perceptive factor and not in reality of human interaction. It is also not an abstraction. Race is there as a perceptive and comparative separation based on human frenzy for supremacy. An example of the super racist could be the German politician and leader of the Nazi party Adolf Hitler (1889–1945) who became the Führer in 1934. He initiated the Second World War invading Poland on 1 September 1939. His regime floated on the undercurrent of racism based on the purity of the Aryan German race with an illusory right to rule the people of inferior races.²¹ Hitler's reference to Aryan race was the founding of the superior most humans on Earth. According to him the purest stock of Aryans were the Nordic people of Germany, England, the Netherlands and Scandinavia. The typical Aryan was mostly defined in all dimensions and characteristics. The system even promoted breeding of the superior stock by selective processes. These historical appreciations show the knowledge deficit as well as paranoia for supremacy in all fields in that period that

²¹The Nazi party adopted and developed several hypotheses on race. The party classified races and conducted various measurements and experiments of population samples just as a matter of Aryan supremacy in the world. Some of the European races thus classified were Nordic, Dinaris, Mediterranean, Alpine, East Baltic, Oriental, Hither Asiatic, Mongoloid/Inner Asiatic and Black. Wikipedia. Nazism and race. https://en.wikipedia.org/wiki/Nazism_and_race. 20 April 2020.

may throw some light while comparing the present with the past and premising the future of racism.

This study looks at humans in six different races based on their physical types though it is not based on physical anthropology but for a global decision-making model in ethnic security governance: Caucasoid, Negroid, Capoid, Mongoloid and Australoid with an addendum by the author based on hybridity—the hybrid sapien.²² The first five are as decided by Carleton S. Coon (1904–1981), the American physical anthropologist.²³ For him the physical characteristics of the races were based on the evolutionary timings of the *Homo erectus*. Caucasoid human is white skinned. Negroid is the widely known “Black resemblance” race based on their skin colouration previously and less commonly called the Congoid that comprised also the short-statured pygmies. Negroid is of mild to dark-brown complexion and curly hair growing from elliptical follicles. Capoid race comprises the Bushmen and Hottentots. Before 1962, they were considered a sub-race of Negroid. Capoid comes from Cape of Good Hope. They are indigenous to South Africa. Mongoloid are the oriental and Amerindian (indigenous people of the Americas) race. Australoids are the Aborigines of Australia and Papuan race. These five races contribute to Coon’s list, but the world today has the new people by genetic hybridisation, the process of interbreeding individuals from genetically distinct populations. A genetic hybrid would therefore carry two different alleles²⁴ of the same gene.

The chosen aspect in ethnic racism is seemingly the skin colour. It also points out the ethnicity of race is based more on human perception than individual mental attributes. The human skin comes in different shades of brown—from dark brown to almost white based on the melanin content. Melanin is a skin pigment in both humans and animals. It makes the hair, skin and eyes appear darker. According to research melanin shields the skin from ultraviolet (UV) rays. Researchers believe that increasing melanin may also help block processes in the body that lead to skin cancer. There are also other factors that influence an individual’s skin colour. The melanin content in the skin also will vary based on the UV protection requirement. Within this assumption people in the tropics will require higher level of melanin than those in the winter latitudes. However other attributes, if any, in human personality based on skin colour is not clearly understood. The last one—hybrid—is the mix of more than one among the original four.

The allele or the games the genes play is not the subject of this study. It is about national security and the role the governments may play in governing it to the maximum. So, returning to the earlier part of this study when two types of early

²² There are many variations of human races based on various studies, but the five types of races mentioned by Coon is taken as the basis for this study to explain about the present-day human as hybrid with one or more of them.

²³ Coon, C.S. (1962). *The origin of races*. Borzon book, Alfred A. Knopp, Inc.

²⁴ An allele is a variant form of a gene. Some genes have a variety of different forms, which are located at the same position, or genetic locus, on a chromosome. Humans are called diploid organisms because they have two alleles at each genetic locus, with one allele inherited from each parent.

humans, one advanced and the other just behind it in evolution, say *Homo sapiens* and Neanderthals, overpowered by the primordial force of orgasmic copulation the hybrid humans, were already prototyped and put on roll on the production line. In other words this study argues in the name of national security, the principles associated with race, and racism had become absurd thousands of years back before the term is invented rather than discovered in the run for prismatic supremacy in human system. Everyone associated with race is almost hybrid, and, if not, they are at least equal in status for a government to consider in governance.

20.2.1.4 Caste

Unlike race, caste is a real distinguisher originally based on human activity since ancient times. Interestingly caste is ethnic differentiation that can merge with race. Mostly caste system as separative factor is based on the Indian caste system. In India it is called *varna*,²⁵ the original Sanskrit word that was not meant or intended to be derogatory or separative. *Varna* explained the division of work in the ancient human resource management without any intended hierarchical connotation in human identification or classification. But it was natural that human hierarchy could set in a work activity as it amounted to the division of work. Hence the more powerful or authoritative work and other forms of influence and identity took control of the less powerful others and people segregated within their own cocoon of activity from generations to generations, strengthening the caste difference in every field. As a distinguishable separating factor, caste system in the human system is visible everywhere.

Every human is active. They are called the active human.²⁶ There is no inactive human unless physically or mentally incapacitated. The active human wants to be, yes, active. Human activities run on two different but parallel tracks throughout the life of the individual except when disabled (see DALE in health security, Chap. 19). One leads to education and knowledge and the other to career. While the education and knowledge or the knowledge phase begins with birth and continues till death, the career phase where one gets into professional activities starts normally in adulthood and may end in old age for most unless disability enters.²⁷ The two phases, at times shifting importance along one's life, make it purposeful. That is all about it for a king with a crown on the head or a pauper with a pan in hand. The similarity in the activity profile is conspicuous. But admission is difficult. The king stands higher than the pauper in activity perception based on authority and pomp.

²⁵ *Varna* meant differentiation of people based on four fields of activities: knowledge (*Brahmin*), executives (*Kshatriya*), producers (*Vaishya*) and workers (*Sudras*). The generations too naturally followed their progenitors. It continues today in a different manner: dynastic continuation of activities.

²⁶ See Paleri, P. (2018). *Human investment management: raise the level by capitalising human*. Springer Nature Singapore Pte Ltd. p. 86.

²⁷ Ibid. pp. 88–7.

The knowledge phase and career phase run parallel. The knowledge phase remains till the end, but the career phase gains importance and priority because of survival needs in between.²⁸ The career phase is more important to personal identity than the knowledge phase because it is more visible and interactive externally (interpersonal). The knowledge phase is more internal (intra personal). The second question after one hears “hello or how you doing” from a person is normally what he or she is doing (for a living)?²⁹ It is the question of identity based on career or professional activity. There lies the caste which is exclusive for each individual today. It may be so in the future. It also means if the cast system is based on activity, in modern times, every individual stands as a caste by himself or herself. The perception of caste has gone much ahead of the *Varna* system. If that is so, the caste system will prevail depending upon what one does mostly in the career phase. It is similar to the roundtable of King Arthur. It was meant to make his knights feel the king considered every knight equal. But the one close to the King sat closer to him. There are many divisions and subdivisions in caste system in society all over the world that looks beyond profession and family engagements.

20.2.1.5 Tribe

Tribe is another social division with various definitions. But for this study, it is yet another term that would have been merged with other differentiations. Tribe is considered a social division based on identified or attached exclusiveness in behavioural culture which in some cases is considered for upgradation through reservations similar to other ethnicities as a government responsibility. Tribes of familiar communities are sometimes linked with commonalities of the chosen kinds with a recognised leader or head of the tribe. A recognised tribe is a formal human system within a nation. It is a subsystem. A tribe is explained under various contexts as a social group. It is also used in anthropology to specify different human systems with exclusive characteristics. A tribe is expected to share a common geographical area, but in modern times, they are distributed spatially in various locations but carry the original tribal names as recognised by the governments and enjoy associated privileges allowed to them. The origin of tribes was as formal human systems of common characteristics and governed by chieftains or similar leaders. They contributed socially in the evolution of larger formal systems by evolving from human bands to larger systems and ultimately to the present-day nations. Anthropologically there are many things common to a tribe—ancestors, culture, enclosed locations, insular lifestyle, etc. Every country has tribes of one form or another. Tribes are sometimes defined or termed as the indigenous colours of a country. The tribes are called in different names, but from the national security point, they are all the citizens of the country they belong.

20.2.1.6 Sect

Normally it is said a sect is a subsystem of religion. This study looks at sects as separate systems from the perspective of governance. One, sects can form under any belief systems; they don't have to be exclusive religious systems. Two, a sect when formed will be more powerful and stronger than its mother group to hold the members together. But this study agrees that a sect gets formed only if there is a primary group more or less identical to it. The reason for the formation could be that the primary group lacked the necessary binding energy to hold people together or did not meet some of the needs and wants of the members that formed the sect as part or similar to its basic and guiding principles. Sects will project exclusive characteristics from its primary group. Sects can be small or large, and interestingly the separative strength of a sect doesn't have to be according to its size and number but the prevailing belief system.

There is a viewpoint among scholars the belief systems of members of a sect are heretical from that of the primary group where heretical means opposing or unorthodox. The author views them simply different and mostly based on interests of the people who formed and subsequently follow the sect. This way one can explain why many ethnic typologies have subdivisions or broken out groups. Sects too are separative factor in a human system, but they still bind with the primary groups. Many such partitions in ethnic formats can be opposing to the primary groups even though they reflect the original and often join together under a common cause. These aspects about the separative forces are common and generally known to people but are extremely important for the governments to know in clear perspective based on situations to make decisions.

20.2.1.7 Politics

Politics is a macro level decision-making format for humans who live in groups being social. Clashes and conflicts are very common in politics-based decision-making systems especially when it exceeds the natural rhythm and forms surges in decision process. Politics is a behavioural aspect visible in all human groups. It is expected to generate the desired balancing force through checks and balances in an ideal situation. Politics can actually improve the binding energy that generates cohesion among members and member groups in a human system. However the political systems in a group or subgroup mostly fall short of the desired objective because of human limitations basically coming from individual as well as group clashes caused by disparate needs and wants sometimes out of sheer vested interests of an individual or a group of humans.

Politics can take shape in various formats. However what is important to understand is that politics, while considered as one of the ethnic separatives (that's why it is being discussed in this chapter), is also the basic element in the formation of a government that is supposed to manage ethnicity which includes what made it itself

a factor. That is an interesting irony. If it is known to all, politics can be understood and transformed as a force of governance from what it is today—the negative catalytic agent of human incapacity that delays progress, instead of being strength to freedom of people. Both the governed and the governing should be aware of this aspect.

Politics is an example of ethnic separation containing fervent criminality sans dignity, thereby promoting hate similar to religion among humans. To that extent political model is identical to religious model. This way politics become as powerful as religion in separating people however close they may be in interpersonal relations and otherwise. In fact according to the author, the political systems are modern religions. They show exact characteristics of religions as in blind belief, fanaticism, criminal behaviour, sycophancy, protectionism, breaking up, discontinuity by interruption and so on. These characteristics can make politics take precedence over nation building and national security governance. A government should understand that politics is a tool of governance which by careless handling can be damaging. Being a tool politics can be used to clean politics itself as in any self-sustainable process—cleaning garbage with garbage.

20.2.1.8 Language

Scholars once believed that language could separate people. They didn't care what God said long-long time ago, "From now on you won't understand what the other person says" (Chap. 17). If that is true, God didn't intend to say language will separate people. Communication can be a problem even in same language. One doesn't know in which language God punished (or is it a blessing?) humans. Whatever, people got it. Otherwise they would not have mentioned it in the testament. But there are people who don't believe that God said it. They felt the world would become a Utopian paradise if every Tom, Dick and Paleri spoke just one language. Accordingly they decided to invent one. God didn't stop them; he knew his curse still held.

The new language was Esperanto (1888) meaning "one who hopes" created by Ludwik Lejzer Zamenhof (1859–1917), the Polish ophthalmologist and linguist. An amazing polyglot, he even designed a flag for the nation of hope. Culturally Esperanto was polish. Many people speak Esperanto around the world today. But it didn't work to resolve the problems of human communication. Alienation and separation still haunt the world in various ethnic conundrums.

An interesting aspect of Zamenhof that the author finds was his earnest interest in making the world a peaceful place that many beauty pageant winners also desire today. But this study doesn't believe in peace as a factual attribute the world can ever gain being an absolute abstraction in the human system. But there are evidences that Ludwik was heavily influenced by the depiction of the Tower of Babel and the conflicts in the world around him during the period. He wrote a drama called *The Tower of Babel, or the Białystok Tragedy in Five Acts*. He was 10 at that time.

The conflicts made the young Ludwik to think that the conflicts were because the people didn't understand each other because the languages varied.

Language doesn't induce hate. But the language can be an in-between in fanning hate through communication overload. There are separations that are artificial and come laced with sarcasm. But the base of such communication is hidden in other ethnic factors. There are language clashes in parts of the world, the roots of which can be traced in trust deficit in authorities. It can be revived by increasing trust, especially between the government and the public. Language simply is a carrier of thoughts in verbal format. Languages will naturally develop or contract depending upon their feed by vocabulary which in turn comes from usage. Usage in turn depends upon user friendliness. Sans semantic dissonances, language should be an opportune tool for governments if used effectively. This also means other languages that are not verbal such as those in the cyberspace.

Language includes all medium of verbal (oral and written) communications including dialects and unscripted languages.

20.2.1.9 Nativity

Nativity speaks of *jati* in Indian systems which can be mentioned as creed, meaning the quality of birth. For some *jati* is a sub-caste; for national security studies, it is yet another separative. *Jati* extends to many other factors such as indigenous original, settler, non-settler, migrant, partitioned, refugee, fugitives, native, non-native, aborigine, inliers, outliers and indefinitely so on. But the *jati* in Indian system is slightly different. It is a combination or an in-between of both caste and creed. It separates people hierarchically based on abstractionist principles with the primary objective of power control by looking on the other. There are a host of "natives" of different kinds that ultimately lead to genetically hybrid human as time advances.

20.2.1.10 Lineage

Lineage is another separative. People of one lineage are considered different from another as higher, equal or lower, thus causing ethnicity in governance. Lineage is the descent from a common ancestor. Lineage explains a line of descendants. A race can comprise one or more lineages of people. The term will be clear if the specific consideration of gotras is taken from Indian references. According to gotras, followed among some groups of people, they are divided based on their lineages from different sages (rishis). It is expressed as unbroken lineage of a common male ancestor (patriline) in the specific Hindu societies. Marriages in the same gotras are prohibited being considered incestuous. It also shows the genetic similarities that prohibit close blood relations to avoid molecular diseases.

20.2.1.11 Age

Age-based separation between people are common in every society, and though it doesn't divide them interactively, it has sociolegal connotation based on the social acceptance and law that is necessary for managing life. Governance of age-based ethnicity is a forte of most of the governments though the laws and support may be different from country to country. Starting with the birth of a human and ending with death, there are governance procedures in both society and government for the babies, children, teens, adults, elderly and dead generally aimed at welfare. There are talks that a nation with old age population may not do well in productive activity compared to another with maximum young population. It is a hypothetical statement. Every human can be productive.³⁰ How they are utilised by a nation is what matters.

20.2.1.12 Gender

Gender is one of the confusing separatives in ethnic security. Governments can be in a gender dilemma if the term is misunderstood. There are quite a few genders with man and woman at the extremes. People generally believe in just two genders: male (man) and female (woman).³¹ There are more in between. References to gender identity, other than male and female, are visible in ancient scriptures and legendary and mythological works. Gender is not equivalent to sex. Sex is assigned male or female based on the appearance of genitals at birth. Thereafter gender is assigned based on sex. But unlike the sex at birth, gender identity of people continues to transform based on their complex interrelationship (1) with their bodies, (2) identities and (3) social relationship. A person's comfort in gender relates to the harmony between the three dimensions. How a person experiences gender depends on how his or her brain plays on it. Gender identity is strictly an internal experience. It can correspond to or differ from the sex assigned at birth. Social gender is the way people display their gender to society by various projections such as clothing, style, taste, mannerisms, interests and so on.

Gender reflects a lot in ethnic security. It is important to understand here that gender is different from sexual orientation what the author calls *sexitudes* to explain a different type of ethnicity in the study of ethnic security in governance. It is also personal; it is explained in the next sub-subsection.

In gender specificity the question is not what it is but what it will turn out to be as time advances. There are broad divides in how we think about gender. It is complex to appreciate under conditioned thinking. The problem in governance is not the gender identities of individuals, but in appreciating the difference by the people in

³⁰Paleri, P. (2018). *Human investment management: raise the level by capitalising human*. Springer Nature Singapore Pte Ltd. p. 97.

³¹In some places sex is also assigned as a third option.

governance and those who are governed. Besides, appreciation of gender identity can also complicate issues when it clashes with sexitudes. Humans have been evolving for a very long time, and gender diversity existed all along. But the issue was never fished out of the Davy Jones locker of the mind, seriously. It remained buried there along with the cable and sinker from birth to death unknown to people in spite of being projected in behaviour. Gender is a fundamental part of human personality development. Gender influences every aspect of human existence. Governance in this case needs to focus on creating space for all to explore and express who they are. Understanding gender means keeping people clear of the myths about gender differences. One of them perhaps crucial to this study of gender is the myth that there are only two genders, male and female that in the system approach is called gender binary. But gender being a “spectrum” is not limited only to the two possibilities. There are many others that are non-binary. All of them are normal unless one feels and argues that “my gender is better than yours”. It is attitudinal. The important aspect here is gender identity, which for a human is the individual sense of one’s gender. Gender identity is what a person feels inside and how he or she expresses it knowingly or unknowingly. There are many such gender identities. It is said that there are more than 50 gender identities besides the standard male and female as is known by sex by birth which in gender identity is termed cisgender male and cisgender female. Cisgender is a term for people whose gender identity matches their sex assigned at birth. Cisgender male is a man who identifies as a man and was assigned male at birth, and a cisgender woman is a woman who identifies as a woman and was assigned female at birth. The term cisgender is the opposite of the word transgender. A person who lives as a member of a gender other than that expected based on the sex assigned at birth. Among other growing number of gender identities, it will be worth mentioning for information in this study about people not having a gender or gender identity. They are called agender people who may describe themselves as being gender neutral or genderless. But the problem with gender identity, as mentioned earlier, is when it leeches into the sexual orientation of the people which is modified in this study as sexitude.

20.2.1.13 Sexitude

Sexitude is the author’s term for sexual orientation and the sexually interactive involvement where the subject or subjects experience sexual, romantic, emotional and preferential desirability and preference. This matters a lot in governance, especially in establishing rule of law and administering human system with concerns for individuals. The term depicts sexual orientations in the ethnic security format. By sexual orientation, it is meant how people see sex and the act of sex in personal lives. Sexual orientation too has different definitions. One of them is the sexual identity of a human in relation to the gender to which they are attracted; the fact of being heterosexual, homosexual or bisexual. It is fine, but the clarification required is about attraction. Is sex just attraction that sometimes may turn to be fatal? Fatal attraction is a catch phrase. This study doesn’t intend to think that way. Sex is not fatal. It is a

hormonal game—testosterone in male and oestrogen in females along with various other supporting factors. Some of them are conditioned. It is also not an attraction but a psychophysiological need by default in humans that needs to be satisfied. Sex during the act is rarely considered as an act of insemination. It could be that way in every form of life though a bit difficult to ask and confirm. The don't-ask-don't-tell policy of some governments takes a downturn as "can't ask; can't tell" here.

Sexitude is a term primarily for use in governance in decision mode. Sexual orientation as a term is more clinical and diagnostic. Whereas, sex is primordial, perhaps the strongest force that leads to procreation. Its main purpose seemingly is for life to continue. When viewed in reverse, sex is the force that keeps life a continuum. Sex is the only force that challenges death. Death looks as if the absolute requirement for life to continue in tandem with the sashaying sexual urge. It can be said life continues through sex and death. One creates and the other clears. Sex and death are more intricately connected than the often quoted life and death. National security looks at both. Sex is a strong stimulus for human in perceived security. Other life forms do not follow the style of human sexuality. They copulate when the urge is not controllable as if it is a routine matter. Humans are not similar to other life forms in sexual orientation even in masturbation though they didn't invent or discover it. This self-pleasuring "alone time" practice according to some is not unique to humans. This study differs.³² Masturbation is not taken as a sexual orientation here. Physically it is with self and very natural for any human. . .well, almost.³³ It is important to note sextitudes are taken exclusive to humans in the study of governing people.

Sextitudes are in different colours and formats. It is not binary. There being a variety of sextitudes can impact demographic predictions. Human sextitudes include the following:

- Heterosexual is where the sexually interactive involvement is with the other sex, which is not of the same gender. It is monosexual.
- Homosexual is where the sexually interactive involvement is with the people of the same gender: male to male (androphilic) or female to female (gynephilic). Mostly today the male-to-male sexual involvement is called gay behaviour and female-to-female is called lesbian behaviour. Sometimes gay may include both the interactions. It is again monosexual.
- Bisexual is where the sexually interactive involvement is with people of more than one gender. Here the word prefix bi refers to binary gender specification—male or female, the two distinct gender forms. Sometimes the term is also referred to as "bi". Bisexuals are sexual interactive with a variety of people of more than one gender identity. They are plurisexual.

³²Kelly, D. "9 animals that masturbate". <https://gizmodo.com/9-animals-that-masturbate-other-than-humans-1723592357>. Accessed 15 May 2020.

³³Masturbation can be an act of the very primitive method of self-procreation when life forms developed from themselves.

- Pansexual is where the person is not limited to biological sex, gender or gender identity. The sexually interactive involvement is towards people regardless of their sex or gender identity. They are also called gender blind, meaning that gender and sex are not determining factors in their sexually interactive behaviour to others. They will have a wide variety of sexual experiences.
- Queer is someone who doesn't like or feel to be confined under one label of sexuality. It is an umbrella term of comfort for all "non-heterosexual, non-cisgender" personalities with the "not this not that" sexuality. They feel comfortable to be known that way even though they could be gay or lesbian and so on. The term also helps those who are unable to identify their sexuality. Thus it becomes a separate, singular and descriptive classification.
- Asexual are those who do not engage in sexual interactions. They have no desire to engage in sexual activity. It is not about sexual dysfunction or celibacy. It is just that they don't want "it".

There are nearly many sexually interactive behaviour patterns dealing with sex, attraction, emotion and preferences among the population. Every one perhaps has his or her signature sexualities. But the term modified for governance in this study is LGBTQIA+ meaning "lesbian, gay, bisexual, transgender, queer, intersex, asexual and others (such as non-binary and pansexual)". This study doesn't include transgender in this term as it is not about sexuality but gender identity. Transgender should be seen separately. The Supreme Court of India in a landmark decision declared transgender to be a "third gender". The judgment affirmed that the fundamental rights granted under the Constitution of India will be equally applicable to transgender people and gave them the right to self-identification of their gender as third gender.³⁴ "It is the right of every human being to choose their gender"; it said in granting rights to those who identify themselves as neither male nor female.

Science is not clear about the exact cause of sexual orientation, though sex always remained a curious case. People who are not heterosexual find criticism, ostracism and discrimination in society. They are serious matters in governance. They are equal citizens. Their well-being has to be a matter of concern. That is where the society needs to practice sexiquette—the etiquette in sexual dealings (Box 20.2).

A person's sexuality matters seriously in a social setup. It is a matter of recognition in the human system. Though it is an individual matter, it impacts on others. But the seriousness under this study is that for the purpose of national security the differential sexuality is seriously natural and not to be seen differentially under discrimination. It is happening naturally to natural people, and it is the message the government may give to the governed so that they can live a natural life as natural people which this study confirms they are.

³⁴BBC. "India court recognises transgender people as third gender". <https://www.bbc.com/news/world-asia-india-27031180>. Accessed 13 December 2019.

Box 20.2: Can Sexitude Be Behind Sexiquette?

Sexiquette in simple terms is the etiquette related to human sexual engagements of the preferred kind where sex and sexitude are consensual. It is about the rules of etiquette in regard to sex in general. Is there a standard sexiquette like “show respect the other” in an interaction in intercourse? Well, unlike the social system interaction, individual sexual intercourse is private unless an orgy. Normally sexiquette is left to the participants as long as the act is not disturbing to others not involved, in which case the social etiquette should normally apply.

20.2.1.14 Education

Education can cause serious disparity among people, but the question is what education is. Educated citizens are active participants in national security issues. Obviously people who are not educated remain passive, and their contributions in checks and balances of governance remain lesser than those with knowledge. To that extent knowledge is part of education. It also means good and effective education. But the problems come when the education system becomes either a part of ethnic difference or a by-product. In both cases the contribution of education in removing ethnicity cannot be underestimated. Education becomes an ethnic issue when it doesn't serve the purpose, especially when the dividers form their own educational system. Incoherent education system thereby damages national security policies.

There are strong links between a country's educated people and national security as education influences all aspects of national security in every element and terrain. There is some opinion that education should remain as an exclusive element of national security. But this study does not find education qualifies to be an element but carries a better affinity as an ethnic divider of people that also stands as a serious contributor in knowledge provided taken seriously in governance. For that the first action for any government will be to take it off from its ethnic façade. The problem is universal. It is not a question of having educational institutions but what they teach and how they teach besides the affiliations.

20.2.1.15 Money and Wealth

Money and wealth are two different terminologies (Chap. 10). Money and wealth separates people into different classes. There are the extra super rich, super rich, rich, middle class, lower class, poor, very poor and below poverty line people all over the world.³⁵ This type of classification segregates people into different classes and social

³⁵There can be people above the super rich whom the author would like to specify as illuminatities who may be proforce or anteforce relative to governance. Illuminatities are the end reservoirs for money.

layers. The interactive matrix accordingly turns the social table against the principles of equity and equality in a human system. Money as it is doesn't divide the society. It is a tool of convenience to manage the needs of life. Money transforms the wants into needs. It makes the demand for pricey things increase to remain different from other people who don't have that much. Money can make social ideologies change by dividing the social system.

The psychonomical aspects briefly mentioned earlier (Chap. 10) can be used to see money as a separator. The divides are caused by how people view money and money flow. It is based on what money represents in the citizen's context with respect to their economic status. Money and wealth are not associated with the human needs alone but human wants in a serious manner. Hence the quality of life and affluence matter considerably to people followed by the great human divide over wealth and holdings. It is not a question whether money is earned dishonestly or honestly. But money has been a symbol of power. Power divides as a proof of power. Interestingly, as projected, the rich doesn't hate the poor as much as the poor hates the rich. This projection usually comes from the poor, meaning money-deficient, as the basic trigger of many political ideologies.

20.2.1.16 Status and Position

The status and position of an individual or a group in a society can decide the authority within. The position is based on the culture and demand for the individual in a group by the rest of the society. The status is the relative position of the individual by authority. The higher they are, the higher will be the authority of the individual in the social system. The level a person holds in a social hierarchy matters relative to the capacity with another. The authority of the individual can also percolate to the group he or she represents.

In ethnic security, position is associated with duties and rights. Social position is also associated with social status and the role of the person in the system. But in ethnic security studies, position and status are considered separately for decision-making in governance as they are guided by different parameters. Position is associated with a social positional structure. Social positions can be visible or hidden. Positions are also divided centrally or peripherally based on the level and situational time.

Position also carries esteem value. The esteem value or prestige varies with respect to the position one holds. A person may have multiple positions, each having its value within the system. A political leader or activist has a high position in his or her party but will also have positions in the country under the constitution as a citizen and in a family as a mother or father. The ethnicity of multiple positions can get mixed up in the highest position of the person who may get influenced by it in the lower position. This means the person may use his or her authority in the government for his family group. The rights and duties or the overall norms associated with a position influence the behaviour of the person in another position. All these

behaviour formats, though natural, will need governance control for balancing the system at all times.

Status in society is relatively associated with the position of the individual in the society. Status is the feeling and outlook associated with the position one holds. Status is a projector in behaviour. Though similar to position in projection, status actually derives from position. Social status separates people in the social standing. The status is a personality ranking by people of themselves based on the social position of themselves and others. There are various types of statuses according to scholars in social science; these are based on position, authority, wealth, knowledge, fame, membership, awards and so on. All these keep changing continuously and examples can be seen all around. More terminologies are likely to come.

20.2.1.17 Role

Role is what the society expects to play in a given status. It can be formal or informal. Formal is the role associated with the assigned duty, delegated authority, acquired responsibility and demanding accountability. These vary from people to people, and accordingly they enact their roles in the society. Though it is difficult to segregate position, status and role follow in a sequence. And so are duty, authority, responsibility and accountability though the separation cannot be accurately calculated. Everyone has activities and thereby roles to play. A man or a woman who is a minister in the government and a parent in a family has two different roles to play as his status shifts between the government and family.

20.2.1.18 Deceased

It may not be clear to many how dead people can be a separating factor in ethnic security studies in relation to national security. Look around, one will be able to see the influence the dead holds on the living in their social lives. The problem with the dead people under such situations is that one cannot tell them to go. So, one gets a position or status with the association of a deceased person at a higher or special level who is dispelled into history, legend or myth as explained earlier. But they also come back and join the rest in matters of governance, carrying their position which sometime may go much forward from what they had before death. But the problems of ethnicity do not stop here. There is also a case of ethnicity between the living and the dead. Sometimes the dead can cause more ethnic problems than the living. There are many examples of dead people coming, calling once a while to cause problems in the society; some of them are frequent visitors on the scene of ethnic turbulence. Who said ghosts are not real! There are good ghosts too—the “fine dead” compared to the “evil dead” who come calling to sort out issues through reference, slogan, photographs, books, play cards, media slots, currency notes, bill boards, t-shirts, etc., everywhere. It becomes an interesting ethnic paradox if the dead refuses to leave or the living group them in for benefits.

20.2.1.19 Occupation

Occupation is a separator creating occupational inequality that may follow patterns that interact with various factors, some of them already discussed, though briefly, in this study. The pattern of occupation can be compared in different dimensions. An example is men and women. Many employers use children in work place, some of them quite risky and dangerous even for adults in spite of the rules against child labour. The fact that occupation is linked with earning for survival makes the majority of people to venture into openings whether they like it or not.

20.2.1.20 Others

There are many other ways a person is separated from another in an inferior or superior mode and equal if the ethnic characteristics are perceived common. The above 19 terms are selected exclusively for this study to explain the ethnic outlook as prescribed here for national governance. There are many others including hyphenated segregation of citizens (Box 20.3). More may come.

Box 20.3: Does Hyphenation Invite Ethnic Separation?

Yes, in national security studies. Hyphenated ethnicity is an identification mark in a society similar to stamping. Stamping is a way of branding for segregation of the commodity or entity. It is explicit ethnicity in the case of humans that may limit governance by well-being unless the government is extremely careful and responsible. Hyphenated identity is a reference to an ethnicity or national origin combined with the name of the country of residence or citizenship. It has negative connotations that may impact national well-being at the end of the day whatever progressive may be the idea and arguments behind it. This study considers removing hyphenation that is equivalent to abolition of slavery even though hyphenation is not equivalent to the latter in legal counts.

20.3 Divided Human

As mentioned earlier, ethnicity is similar to reflections in a hall of facing mirrors. They go on till the ultimate end of ethnicity—the human as a being. In that case one wonders, “Isn’t each individual human an ethnic miracle?” From such vantage point, this study looks at ethnicity as an amazing diversity of humans rather than a curse to human system that separates people. The curse is in the selective script; that can be changed. In fact the human differences should unify the system. It may, in the course of time. Ethnic security is about disparity among the population of a country under various situated categories. It is not just about religious difference, casteism or

racism. It is about every aspect of differences and subsequent changes in interactive behaviour in which one is subjugated. It could even happen within a subsystem—an organisation, sports field, educational institutions, military, etc. (Box 20.4).

Box 20.4: Hurry, You Sons of Colies and Bitches. .³⁶

...shouted Commander F. W. King of the British Navy at his Indian ship's company of HMIS *Talwar* of British India; it was said. The response was the (in)famous mutiny of 18 February 1946. It had the ethnic taint. It made the ship's company to go on a hunger strike that turned violent. The ratings experienced a sense of subjugation. They felt they were fighting someone else's war in the Second World War. The strike and violence engulfed 74 British warships, 4 flotillas and 20 establishments from Kolkatta to Kochi to Karachi in hours (during a period when there were no cell phones or e-mails). The mutineers pulled down British flags from warships and facilities and chanted nationalist slogans. In the aftermath, 200 lives were lost; thousands lost their jobs; 2000 were arrested and incarcerated. Though their fight for rights was not officially acknowledged, their acts were recorded in the history of India's freedom struggle. But it was more an ethnic riot and a threat to the government of the colonial India than a full-fledged freedom struggle. But it showed the divide among humans.

Consider the shape of the Earth for this study as slightly ellipsoid glass jar relative to humans who own it. Then consider each human system with its own characteristics and differences as a million plus marbles each containing identifiable human systems one different from and dissimilar to another in divided fragments of each genetic bubble. This forms a divided human system. This division is the ethnic dot on which the separation and thereby the ethnic security depend up on. The marble jar with a lot of marbles showcases the divided human systems which will reflect further thousands of years from now in isolated systems. This study, thereby, concludes human system as marbles in a jar called the Earth. Each marble thereby is a divided human system with many smaller marbles within.

In an ethnic world, the human beings live in divided societies and alienated mental communes. It is natural and cannot be changed in a world that is varied in human outlook and perception. The world that way is ripe for ethnic riots in an asymmetrical plane devoid of containment measures. A riot kills, injures and displaces people for reasons of being divided with trauma that may last for generations. For example, the victims of India-Pakistan ethnic divide in 1947, the world's largest cross exodus in history, may carry it for generations that will reflect in their interactive attributes for centuries. That was perhaps the largest case in the world for

³⁶Shah, Aditi. "Mumbai and the Great Naval Mutiny." <https://www.livehistoryindia.com/snapshort-histories/2017/08/13/mumbai-and-the-great-naval-mutiny>. Accessed 1 February 2019.

failed governance.³⁷ Ethnic divide and consequences are serious. Some of them are positive. Quite a few of the displaced on both sides of the divide in the India-Pakistan imbroglio of 1947, though upshot of the absence of leadership and failed governance on both sides and among other stakeholders such as the British, are economically well endowed wherever they are in the world as if they got to build up all that they lost during the partition and more. It is a psychological blow off that may carry them richly for generations. More than the wealth accumulated, it shows a subconscious reaction to the lasting impact of the trauma of ethnic divide. The insatiable hunger for accumulation of wealth is a positive outcome of the trauma of displacement and loss. Everyone wants to recapture everything and more than they lost.

It is a common perception that violence is integral to ethnic security. It has become impossible to visualise ethnicity without violence. It seems to be a myth that ethnic security is always confronted with violence. While ethnic divide may have its violent outbursts, it is the simmering discontent and potential difference of vacillating emotions of the divided humans that are the concern in national security studies. Violence is the end result where ethnic security destroys itself. It is the pre-violence stage that is crucial for ethnic security management.

Here the question is “what is ethnic in national security?” Ethnicity in national security studies springs up from all that contribute to human divide—communal, cultural, national, religious, tribal, caste, racial, gender, origin, age based issues, etc.³⁸—that threaten the integrity of a nation, loosely said, the secular character of a nation. Still it goes beyond that. This consideration is to bring in all the agents that contribute to divisions in a human system, which is essential while considering national security. According to this understanding, the divisive agents could be different in different countries. They have to be identified as the first step in handling ethnic security. Such a definition also avoids ambiguity with respect to other known principles of ethnicity quoted in different contexts. For example, in the Genocide Convention and in general lexicography, ethnic groups are considered to be different from three other groups—national, social and religious.³⁹ Whereas, in this book, the term “ethnicity” means the all-encompassing terminology that marks the difference

³⁷The partition of India and subsequent events showed the poor quality of leadership and incompetent governance prevalent in those times not only in the two countries but in the entire world. There is nothing good to talk about the leaders and governments of the period. The particular incident specifically pointed out the poor quality of leadership in India, Pakistan and Britain, and generally in the post World War world. There was absolute confusion all around the world. The result was human suffering or rather dismal absence of human well-being. No leader of that period deserves any praise in history from the perspective of human well-being, the subject of this study. The leaders enjoyed their lives as long as they had them. People burnt in hell on Earth. The reprieve is yet to come, hence this study.

³⁸United Nations Development Programme. *Human Development Report 2000*. Oxford University Press. p. 1. According to the Report, one of the seven freedoms is “Freedom from Discrimination”—by gender, race, ethnicity, national origin or religion. In this study, the author chooses to confer discrimination by all means to one term: ethnicity.

³⁹Adam Roberts and Richard Guelff. (eds.). (1989). *Documents on the Laws of War*. Clarendon Press, 1989), p. 158.

between humans as individuals and groups by every order of difference in a nation system, past, present and future.

At the threshold of the twenty-first century, the contemporary world is witnessing ethnic conflicts of different kinds. These conflicts have been attributed to the lack of statesmanship and governance, paucity of reasonable leadership among ethnic and religious communities, persistence of inappropriate security measures, and complacency and ignorance of bureaucracy. It is a cruel predicament for the world. The dead end of the road in an ethnic conflict is probable micronisation of the nation state. At the lower side, it is just restlessness and loss of productive ambience in the psyche of a state. Little attention was paid to ethnic issues in history. It was inflamed on many occasions to support military campaigns. The neglect continued during the Cold War. The impact of ethnic issues in the world affairs were dissolved in the Cold War. The developing world was misguided, and ethnic issues have overtaken in a stunning fashion. It is more visible after the Cold War since the curtains are drawn for a wider view of the world subsequently.

Communal issues originated from ethnicity could also be seen as part of a larger agenda of fundamentalisation of the world. Every nation is subjected to it. It is, therefore, essential to safeguard the interests of a nation to retain its identity. There is the age-old belief that shared values and security strategies can reduce ethnic conflicts.⁴⁰ Ethnic problems are not related to terrorism. It can be caused by demographic formulation, belief systems and demographic dynamics. Potential ethnic and territorial conflicts also emerge when economic reforms are not successful.

Tolerance among the majority of the society, global concept of education and integration of marginal groups into society through job opportunities and education are the stereotype remedies. Early warning systems may give time for preparation, the most important ingredient in the ethnic security action plan, in case methods of integration fail to yield result. Economic crisis and revival of nationalistic feelings among the young generation by indoctrination or otherwise can fan the flames of ethnic insecurity. The process of unification can mean losing of identity for such flamethrowers. Wars can result in such cases and there are no acceptable world bodies to intervene. The problem becomes serious when ethnic groups lose touch with global values. Education is a solution, but conditioned ethnic pangs cannot be controlled by mere education alone. It also means how one defines education.

Ethnonationalism, fundamentalism, militant secessionism, militarism, territorial disputes, national chauvinism, economic deprivation and gender-biased insecurity are all factors that affect ethnic security. There are millions of victims of such conflicts all over the world including women and children.⁴¹ The result of xenophobic nationalism that breaks into ethnic security is militarism and suppression. A

⁴⁰“How can Shared Values and New Security Strategies Reduce Ethnic Conflict and Terrorism?” www.geocities.com, July 2000.

⁴¹Beauchemin, E. “Child Soldiers of Liberia.” www.mw.nl. May 2001. According to reports, there are 300,000 child soldiers in 30 countries in the world (2001).

selective human security approach would go further and broaden the value of security to privilege the ethnically marginalised humans. The policy of the government should vacillate to see uniformity in a social structure based on the divide among humans.

Children are ethnic entities in ethnic security studies. Children are ethnically different from adults in their life towards adulthood. Their experiences are different. The abuse of children is multiple in counts. They face abuses even from religious people. A study in the United States has shown that thousands of children are abused by the Roman Catholic Church over the past 52 years. One every ten priests was eventually accused of child abuse. According to studies, the human toll amounted to 19,667 children abused by 4392 priests from 1950 to 2002, and the studies caution that even that could be an undercount.⁴² Priests are not alone. Children get abused at every stage of their lives in every which way including sexual abuse by all kinds of strange animals of the *Homo sapiens* variety not excluding parents and close relatives. Fortunate among the victims end up in psychiatric wards. They are hopeful of a cure. Others, the majority, grow up with the trauma untreated to vanish in the make-believe world.

The worst issue of intolerance comes from gender bias. Women from the beginning have been a suffering lot in spite of being superior to man by design. It continues beyond time in the entire human society in varying degrees across the world. Isolated voices against ethnic divide based on gender surfaces at times, though. Female poverty and discrimination is a serious subject of gender divide. The position of women, according to indicators, within subsistence economies is declining and becoming increasingly insecure.⁴³ Women's access to resources continues to dwindle in subsistence economies. At the same time, there is increasing demand on their time and physical energy from the male world. This is equally applicable to rural and urban women. The demands include sex at will of the male. The absence of male libido (including geographical separation) is another serious problem for the female. Sexual repression is more common among women than men. The problems associated with the absence of such needs, abuses and other repressions in women have made them a community in depressive dejection in many parts of the world including the educated and affluent societies. Women of the world are impalpably angry; it is a simmering feeling reflected in everything they do under ethnic divide with men.

Women in a family make up for the lack of services for the family members that the government has to provide. This is extended to girl children who often end up supporting their mothers in sharing the demand on them. The result is deprived education and quality life even in affluent systems. There is also rapid population

⁴²Goodstein, L. "US Studies Cite Abuse by Thousands of Priests: Number of Child Victims Put to 10,667." *International Herald Tribune*, Bangkok. 28-29 February 2004, p. 2.

⁴³Jacobson, J.L. "Closing the Gender Gap in Development." In Linda Starke (ed.), 1993). *State of the world: a World Watch Institute report on progress towards a sustainable society*. W. W. Norton and Company. pp. 75-76

growth in subsistence economies attributed to women's lowered status.⁴⁴ The conditions also reflect in the health of women. Women and girls automatically fall within the trap of neglect and decline in this manner in subsistence economies. Dowry demand is a symptom of gender differences. Whether it is one way or the other, it is discrimination. A lady friend from Kerala, India, once mentioned, "My husband took only 75,000 rupees (around US\$ 1650) from my father towards dowry; very cheap, no?" That is an understatement of accepted discrimination. The woman has accepted it but feels she received a better deal than other women in the marriage market. Ethnicity by gender prevails in the statement. The governor of the Indian state of Kerala, Arif Mohammed Khan, took an unprecedented action to go on a day long *upavas* (fast) on 14 July 2021 in protest against dowry demand and harassment of women in the marriage market and thereafter.⁴⁵ Kerala, interestingly, is the most literate state in the country. But the act of the governor shows the state of women there.

There is a tacit acceptance by women that they are not free in marriage in many societies under male domination. Marriages in such societies where women are owned by some, as bonded humans, are demeaning for the female human species (and their parents) in its real sense irrespective of literacy and modernity. Unfortunately, there is no cure since such practices tend to become accepted normals in the course of time. There are odd revolts, though. Often they end up in disaster for the women. Suppression is the name of the game that males play with the females in the ethnic gauntlet that extends even to procreative acrobatics. Is it natural? Is it necessary for the male to survive as a hunter? To that extent, is there a hidden meaning of survival in every ethnic game? These are late night thoughts for the weary and dull. They are gritty and dark. There are millions of women who at the end of a physically and mentally exhaustive day cannot close their eyes to fall asleep until performing their last duty of the day—serving to the libido of their husbands or masters who return from the "hunting" fields of modern society with or without success. Whether the male species succeeds in bed to get it straight or not, the female still have no choice but to wait for the end result before committing to sleep—the only cure for fatigue. (No wonder in some species the female devours the male at the end of the act. . . QED!) In the male bastions of insecurity, the libido is fragmented. In most of the cases, libido is not in tune for both the individuals at the time of the act, and the role of the women is that of a provider. And they do it more as a ritual than an emotional union with their sexual halves.

⁴⁴Ibid. p. 75.

⁴⁵Two weeks before, the governor had visited the parents of a woman, who allegedly died by suicide in her husband's house in Kollam after facing harassment over dowry. Harassment to women is rampant in the state. "Kerala Governor to observe day-long fast against dowry." <https://www.hindustantimes.com/cities/others/kerala-governor-observes-day-long-fast-against-dowry-101626235077593.html>.

Victimisation of women based on gender bias does not end up in the dowry system alone.⁴⁶ There are many other social quicksands where women and the girl children get buried silently. Midwives with the connivance of doctors swap children in hospitals for a good sum of money—ranging from a hundred to 300,000 rupees in India. The unsuspecting parents of a newborn boy child may never see the child in their lives, because it has been swapped for a baby girl just born to another parent who bought the boy for cash and exchange. Only the midwife and the doctor will know.⁴⁷ The gender bender, cultural trap, religious strictures, social systems that institute taboos of yore, physical incompatibility with men who are more muscular and emotional than women, privacy requirements, etc. are all matters of discrimination of women. It goes on in spite of mostly silent protests from women. The gender bias is razor sharp world over. The world can bring in a solution to this problem only if it understands what women want. That equally applies to the national governments and may vary from nation to nation. Ironically women are the superior sex. It could be a natural selection to survive under intense discrimination.

There are societies where women are killed for honour. Honour killing is legal in Jordan. Article 340 of Jordan's criminal code states, "A husband or a close relative who kills a woman caught in a situation highly suspicious of adultery will be totally exempt from (any) sentence". Article 98 guarantees a lighter sentence for the killer of the male involved in relations with a female who have committed an "act which is illicit in the eyes of perpetrator". The concept of women as property and honour like a domesticated animal of economic importance is deeply entrenched in the social, political and economic fabric in many nations and societies: In Pakistan honour killing is called *karo-kari*.⁴⁸ Honour killing issues have been reported from developed countries also. A Sikh in the United Kingdom was accused of hiring a hitman to kill his daughter and her Jewish boyfriend to protect the family's honour after the couple ran away together.⁴⁹ In India, a girl child has 40% more chance of death before the age of 5 than a boy because she is unlikely to be taken to a doctor if she is sick unless she is seriously ill. According to reports, the health expenditure is 2–3 times more for boys than their sisters. India has a very high rate of neonatal and childhood deaths of girl children.⁵⁰

⁴⁶ A television (TV) channel in India showed the charred body of a village woman who took her life by immolating herself (22 October 2004) in India. The news announced that an intruder raped her in her house. The society thereafter shunned her. She had no choice or will left to live. She killed herself. Such stories and atrocities against women are abundant in the world today. It is not isolated to India. Gender inequality and female vulnerability against men are serious ethnic issues of differences.

The partition of India in 1947 has seen the world's largest cross exodus of ethnically divided humans in the comparatively recent years. It was not the fear for life and property that made them move suffering all odds. The underpinning fear was that there would be no opportunities for their growth, development and advancement in life for generations in the country that explicitly rejected them. Humans, under the strong control of their needs, do not want to just exist; they want to do something out of their life. When left out of their aspirations, people will naturally look across the borders. Such movements are seen today all over the world without any geographical partition.

In the world of divided humans, there is exploitation of the insecure by the relatively secured. It is seen everywhere—from gender bias to religious conversions to super wars. The bottom line of ethnic security is preventing this exploitation.

20.4 Divided System—Isolated Human

The isolated humans belong to a different genre altogether. They are generally known as the indigenous people in the social vocabulary of the world. The question here is not what they should be known as, but are they a formal part of ethnic security management? The answer is positive because they, as per the definition of this book, certainly fall within the divided human system in an isolated manner and not in an alienated fashion. They are restricted people. They have no serious participation in the community, and, besides an odd revolt or interactive conflict with other communities, there are no serious problems of national security except that they tend to be forgotten as the citizens of a particular nation even if they do not know the name of their own country. These are also not the people of the so-called arrested civilisations. They are the natural people of a habitat who are isolated by their own will *ab initio* and continue to be that way today without any intention to merge with the commons around them. Their time and place in history are different from other fellow humans around them in various parts of the world.

This does not mean they are not involved in national activities. They are very much there, especially today, participating as responsible citizens. But still the isolation of centuries is writ in their attitudes towards a life within a nation state where others, according to them, are outsiders. These people are found in every part of the continent and in most of the countries. They are still fighting for their ancestral territories in most part of the world. In certain areas they have withdrawn to the left over or reserved territories. Their size is dwindling not by discrimination, but by the general lack of concern on the part of governments. Indigenous people need a better deal than what they get now. They are not in a position to take care of their needs themselves.

Under the human rights, states are required to protect the interests of indigenous people to preserve their cultures. But in reality, all over the world, there is serious dismemberment of these cultures. It will be disastrous for the world if the indigenous cultures are allowed to vanish, because under biodiversity, the ecological health of

the world cannot be sustained without indigenous people. Biological diversity is linked with cultural diversity.⁵¹ The interesting aspect of ethnic diversity is that the world will not be able to manage its sustainability without ethnic diversity that includes the isolated humans—the indigenous people. The indigenous people, though isolated in a way, are not just primitives. Their range varies from the most advanced, like any other human in the world, to the primitives who may even practice cannibalism. The advanced among them fight for their rights to protect their territory in the court and parliaments, whereas the least advanced just keep away from the civilised world and withdraw to their territories behaving violently against strange intruders. They, however, do not have the organised support in their existence. It has to come from the government. Such people are also called “natives” or “tribals” in some cases. The indigenous peoples are original (inliers or in Indian term *adivasis*) to the territory. The rest of the people around their territory, in their own country, in most of the cases, are the descendants of powerful outsiders (outliers) who occupied the territory pushing them to a corner. Their culture is distinct from what is followed in their country. It is estimated that there were around 190 to 625 million indigenous people in the world in the 1990s. The range is wide because of varying definition of indigenous peoples.⁵² According to studies, cultures of indigenous people are dying faster than the people who belong to the culture. A pointer is in the Americas. There were about 54 million indigenous people in America when Christopher Columbus (1451–1506), an Italian explorer from Genoa, landed on 12 October 1492.⁵³ The population of Europe was around that figure at that time. Five centuries later, the population of their descendants is 42 million.⁵⁴ Their culture almost vanished along with their natural habitats. The conditions are more or less similar with the indigenous people of Australia, New Zealand and Siberia.⁵⁵ According to World Watch report, India has the largest population of indigenous people followed by Myanmar and Mexico.⁵⁶

20.5 Ethnic Riots—Violence in Primordial Form

An ethnic riot is intense and sudden, often well planned when an ethnic group attacks another. It is engulfed in primordial violence. Such violence has many names—communal violence, racial attacks, religious wars, linguistic agitations, tribal disturbances, political violence, etc. Often, the riots are premeditated and vindictive sans any condition of remorse in the participants who believe in their deeds firmly. Often, they are back to repeat the act in a chosen manner. It can be controlled by the state. But the state may lack the competence and determination in most cases. Denial of opportunity could be a form of ethnic violence prevention for a state.

According to author Donald L. Horowitz, a riot is both cause and effect and a process that has its own dynamics. As a cause, a riot exacts its toll in casualties.⁵⁷ The death toll can range from a few to hundreds of thousands. Among all the riots, the 1947 India-Pakistan partition riots acquired maximum dislocation in life; the toll was between 100,000 and 200,000 dead and about 10 million rendered refugees. It was unparalleled to any kind of human movement or exodus in history. The refugees were brutally attacked by disoriented savages of faith of their own genre, violating all norms of civility. The effect of a riot is not only savage death but also displacement of people internally and externally—creation of refugees. Their numbers can swell across borders. Such movement of people is the very purpose for a riot. Displacement is the key issue, and the cause is made effective by primordial violence ending up in the mayhem of murder. Nothing displaces so many people like an ethnic riot. It affects demographic security very seriously because of displacement and movement of people.

Ethnic violence today is also the proving ground for militant activism. Such activism can provide leadership in ethnic violence.⁵⁸ The outcome of ethnic violence is private armies, militant leaders and violent political groups that may cause additional harm. Such violence will be a cause for separatism, fragmentation and micronisation of a country in the long run. Ethnic violence can wedge the planned growth of a country and turn to secessionist wars. The effect of a riot is very discernible. It is not a free-for-all confusion within a crowd. The attackers and targets are identifiable.⁵⁹ A riot is normally planned much in advance. It is not a casual or a spur-of-the-moment affair. It is an invasive war in a limited space. They resort to even war cry in certain societies. An example is the Zulu war cry in Durban, South Africa, when they attacked the Indians with an intention to destroy them and all that belonged to them. The attacked may try to defend, often without success. Success is decided on the counter-attack. It takes place often after a lapse of time in the same place or another. The counter attack is also lashed on to innocent victims identified with the original attackers. And the riots go on until the state intervenes with force. There are many cases where the state fails to intervene for reasons of

⁵⁷ Horowitz, D.L. (2001). *The deadly ethnic riots*. Oxford University Press. p. 9.

⁵⁸ Ibid. p. 11.

⁵⁹ Ibid. p. 12.

ethnic politics. In such cases, one party gets victimised totally. Sooner or later the state will have to intervene as ethnic riot will spread out of proportion or disrupt and damage other aspects of life in an incalculable manner. Often, such attacks draw the attention of international community and organisations, and the state will be under pressure to react. There is a common misconception that the state could be helpless in the face of a riot. It is never so. In almost all the cases, a state has sufficient power and strength to quell any kind of riots. The Tiananmen Square⁶⁰ incident in China is an example of the might of the state. Sometimes a state may use overwhelming force that may invite international criticism. Riots in a country can also be geostrategically engineered by interested parties under deceptive and coercive policies of diplomacy. Such policies damage the geostrategic security of the perpetrators in the long run.

The attacks in an ethnic riot often involve extreme violence and sadism. Victims are killed in the cruellest manner, spewing venom of vengeance. They may be burned alive, slashed or hacked to death. Sexual perversion is very common in certain cases of extreme hate-induced riots. “Lacerated penises of the murdered men stuffed into their mouths, or the mouths of their murdered women”, writes Horowitz in one such case.⁶¹ The painful aspect of ethnic riot is self-assertion and justification even by those who are not involved. Condemnation may come officially, but not universally. Condemnation may take many years. The genocide of the Jews during World War II by the Nazis is still talked about with a sense of disagreement and disapproval. It is likely to linger on for a considerable period into the future. What reflects in an ethnic riot is the clear and present antipathy and intolerance in a social system where every human looks at an identity external to him. This is seen in the regularity and striking similarity among riots in the world as a general phenomenon and not exclusive to a particular society. It is a faithful reflection of tenuous human relations and the fragility of existence within which the concept of national security can asphyxiate.

Ethnic riots follow their own belief systems the world over. There are many such belief systems:

- The government is supportive to ethnic conflicts. This is the conclusion if the government is not seen as the target.
- The law enforcement machinery either supports it or remains non-participative.
- The ethnic organisations are supportive to it.
- A neighbouring country or its agents must be supporting such riots.

⁶⁰This is an example of the power of state against organised mass movements challenging its policies or motives. The Tiananmen Square incident was not a riot situation, but a massive rally that started as a peaceful march of students advocating democracy and freedom. The Tiananmen Square is one of the large public squares in the world situated in Beijing, China. Students gathered there chanting slogans of democracy. The government called in troops after negotiations with student leaders failed. The peaceful demonstration turned to violent attacks on the forces. The demonstration was suppressed by brutal use of force on 4 July 1989 (was it a coincidence that it was the Independence Day for the United States? Is there a geostrategic message in the demonstration and suppression? Was it a covert move? If so, who backed it?).

⁶¹Horowitz, D.L. (2001). *The deadly ethnic riots*. Oxford University Press. p. 13.

- The powers of the world can be parties to it.
- The superpower is a party to it.
- Everything is related to religion.
- If it is fundamentalism, it must be Islamic.
- An ethnic violence will always be followed by new violence after a lapse of time.
- There is absolute silence in describing ethnic violence in its true perspective except some lone voices in responsible media.

In reality, these belief systems are out of place in the evaluation of ethnic riots, though they may serve as hypotheses. There are many myths in ethnic security governance. The cause of each riot has to be identified before arriving at a conclusion. What gives away the dynamics of riots is the organised and structured violence. Confusion in riots is only external pretence. It is this appreciable structured behaviour and dynamics of a riot that make it more amenable to containment by law enforcement forces, provided there is political will. Political will is the bedrock of national security. With a regime in place that has the political will to handle the issues, an ethnic riot can be prevented. Absence of political will to contain and control a riot is the result of temporary dislocation caused by the riot situation itself. It happens in an unprepared situation. Often, this incapacity of the state is misunderstood as support to riots. Incompetence in governance including leadership failure too adds to the tragedy.

Horowitz's observation about the cause and effect of the riot also extends to the process. The riot process is also patterned.⁶² There is always a preparation period, and also the participants of the riot may make it complicated by divergent motives where the group behaviour sometimes gets overshadowed by individual interests. The effect of the riot—arson, murder, lynching, looting, rape, mutilation, etc.—is mostly governed by these motive fluctuations among the individuals within the group who initiates the mayhem. The complexity of a riot is based on individual motive fluctuations in a group. None of these complexities, however, makes an ethnic riot a non-structured activity immersed in confusion. The disorder associated with ethnic violence is very “orderly” and systemic.

Ethnic riots within the ambit of ethnic security involve only those aspects that are related to structured ethnological conflicts involving violence between dissimilar human groups within a nation or under circumstances related to a particular nation. An external terrorist attack even if based on ethnic issues is to be considered as part of a different element of national security. Ethnic attacks on the people of a particular nation come under the category of ethnic violence, even if it happens outside the boundary of a nation. In the sense of national security, it is more the concern of a state about its people than that of international organisations. It is an internal matter in primary treatment in the maximisation of national security objective. A terrorist kills as a matter of policy, whereas ethnic violence is a matter of internal hate, and

⁶²Ibid., p.16.

there is a clear selectivity of the individual human target. There is a difference, though not easily discernible.

Humans are killed by humans (homicides) more than any other external causes except for mosquitoes which are vectoral, not direct like death by snake or scorpion bite. History is replete with homicides as if there is a law of nature and periodic target assigned to humans to eliminate own species. This also brings out the finding that humans are probably programmed genetically to kill other humans and self (suicide). Majority of killing of own species take place under ethnic hatred and rivalry or rather ethnic phobias (Box 20.5). The trend in homicides may provide a trail leading to the intellectual evolutionary pace of the unitary civilisation and its worm tunnel forward. Table 20.1 gives some of the violent ethnic riots in history for a random look academically. Most of the ethnic riots are pogroms—organised and planned killing not abrupt or thoughtless.

The table shows the human system is riot prone. Some of them are planned and some sporadic. The motives can be varied. It is a difficult job for governments to eliminate riots. Ethnic security strategies need to be modified and applied accordingly by responsible governments. The observations show the following:

- Fear-induced insecurity holds the key in ethnic separation.
- Riots are based on every agent of ethnic separation or instinctive behaviour based on situations.
- Riots are anchored on violence and thereby considerably localised.
- The world is a cauldron of insecurity-based hate moves reeking in vengeance.
- Riot moves can be low to extreme.
- The perpetrators may not be aware of the real reason, but participate instinctively.
- Mental and emotional health of rioters and those who instigate them are at the rock bottom; they need personality makeovers.
- Riots happen where governance is weak in ethnic security and could also be supported by agencies in government and other authorities.
- May be triggered by the built in genetic insecurity.
- Riots will continue in the human system in accordance with the law of invariance; therefore preemptive or preventive containment could be a better option, not elimination.
- The human system all over the world shows singularity and differentiability in similar approaches and modes. But still, the method that suits one may not suit another. It is for the governments to examine.
- Insecurity and hatred is contagious, hence ignites continued vindictive behaviour for the life of the human system involved, carried forward to generations.

The table shows that ethnic violence was quite frequent in the recent past. It is also an indicator of the future. It is systemic and regular. The anatomy of ethnic riots is mounted on hate. The whole world is involved. The indication is that it will continue and the nations have to find comfort within this perceptual reality. Riots are premeditated with good funding to provoke and participate. Rioters are primarily internal mercenaries involved in hate campaign with a cause. In odd cases there could also be people on hire from outside. Ethnic riots when highly organised

Table 20.1 Random lethal ethnic riots in history^a

Year	Country ^b	Nature of riot
44 BC	Rome	Post assassination of Julius Caesar
532	Byzantine	Nika sedition against emperor Justinian
1066	Granada	Massacre of Jews by Muslim mob
1196	England	Poor riot
1298	Germany	Rintfleisch massacre of Jews
1349	Germany	Strasburg killing of Jews by burning during Black Death
1391	Spain	Massacre of Jews
1506	Portugal	Massacre of Jews
1648	Moscow	Riot against salt taxation
1662	Moscow	Copper coin riot resulted in brutal suppression
1706–1707	Scotland	Treaty of Union to annex Scotland
1894–1896	Turkey	Killing of Armenians
1905	Russia	Riots in Odessa against Jews
1915	Turkey	Killing of Armenians
1930	Burma	Between Telugu and Burmese labourers
1938	Burma	Simmering violence
1941	Romania	Anti-Jewish riots in Bucharest
1945	Nigeria	Between Hausa and Ibo in northern Nigeria
1947	India-Pakistan India	Hindu-Muslim riots subsequent to partition Sikhs attack on Muslims in the Punjab
1949	South Africa	Anti-Indian riots in Durban
1950	Singapore	Violence against Europeans and Eurasians
1953	Pakistan	Anti-Ahmedi riots in Punjab
1959	Zaire	In Luluabourg
1962–1963	India	Jabalpur riots. Hindu-Muslim
1964	Singapore	Malays against Chinese
1966	Nigeria	Anti-Ibo riots
1967	Malaysia	Anti-Chinese riots in Penang
1968	Mauritius	Simmering violence
1969	Malaysia India	Anti-Chinese riots in Kuala Lumpur Anti-Muslim riots in Ahmedabad
1977	Sri Lanka	Sinhalese and Tamils
1978	Turkey	Anti-Alevi violence
1979	India	Nagas against Nepalese settlers in Assam Violence in Jamshedpur Violence in Aligarh
1980	India	Violence in Tripura
1981	India	Hindu-Muslim in Bihar Sharif
1983	Sri Lanka	Sinhalese and Tamils
1984	India	Anti-Sikh riots in Delhi post assassination of Indira Gandhi
1971–1972	Philippines	Muslims and Christians
1972	Burundi	Between Hutus and Tutsis.
1977	Sri Lanka	Between Sinhalese and Tamils.

becomes ethnic warfare. Examples are the so-called ethnic cleansing of the 1970s and 1980s in Eritrea and the 1990s in Liberia, Bosnia and Georgia. The line between ethnic riot and ethnic warfare is often difficult to identify. Rioters have their own version, and it will be different from that of the analysts of the neutral kind. The government's view will be more deviated and will be based on the political decision process. Decision-making will require a balanced view. Riots are followed by rumours. It is important for the governments to understand the damage the grapevine can cause in the form of rumours. Here, ethnic security finds a correlation with another element of national security—informational security (Chap. 17). Close coordination of the element of informational security with ethnic security may be able to control ethnic violence in a community.

Arson is an all-rounder in ethnic riots. There is also savage cruelty in handling the victims' bodies. Bodies may be mutilated or insulted after killing. There will be laughter when dealing with helpless victims under hate and cruelty. Psychologists attribute all these cruelty to the release of accumulated aggressive energy.⁶³ Suppressed and unfulfilled ambitions fuel the expression of cruelty in such situations even in the meekest of the rioters. Violence is primordial, and symptoms of primate life are evident in every ethnic riot as seen in the treatment of victims and cruelty at the aggressive moment. Mutilation that too based on phallic symbolism completes the desire for total control of the victim. Humiliation is a sign of positive control that the psychology of the perpetrator desires in a crime.

Ethnic security becomes a serious issue when there is state neglect against a particular ethnic group or order. State neglect slowly leads to persecution of other groups basically aimed at suppressing them out of fear that they may gain control if otherwise. There are no solutions for state sponsored ethnic insecurity. It is an irony in national security management and can be done only by those states where the concept of national security is not clearly understood or the governments perform under decadent belief systems. The international community, in support of ethnic security, excoriates such countries through reports. Most of the countries orient the subject to religious issues, whereas ethnic security as an element of national security correlates all aspects of human discrimination. Ethnic violence is not restricted to a particular country or regime. It is common. India, the world's largest elected democracy and the innovator of non-violence as an instrument of power, is ethnically postured as a violent country. The National Integration Council (NIC) was a major apex body in India that looks into frayed communal tempers as a sane advisor. It was constituted by Jawaharlal Nehru, India's first premier against the backdrop of various communal riots in India. According to reports, the problems of ethnic insecurity are rampant in India in various forms.⁶⁴ The NIC hasn't been of much use in resolving issues. The case in India is different from elsewhere. Poor and

⁶³ Horowitz, D.L. (2001). *The deadly ethnic riots*. Oxford University Press .p. 116.

⁶⁴ Engineer, A.A. et. al., in Letter to the Editor, *The Indian Express* (Mumbai), 3 May 2001, p. 6.

depressed minorities⁶⁵ are vulnerable and therefore highly volatile. The recorded social conflicts are among religious, linguistic and caste-based communities. If education is increasing aspirations, economic growth is enlarging economic opportunities and political democracy is resulting in increased politicisation, then one can expect more such conflicts among various social groups according to social commentators.⁶⁶ It depends upon the capacity of the political institutions to prevent and manage such conflicts. It is also necessary to see the underlining idea of a nation state is not jeopardised by territorial instincts and affiliations of such groups to international groups outside the purview of the country.⁶⁷ This will increase problems of conflict management since there will be external ties. For these reasons, ethnic security involving all groups of people is to be seen as a separate element of national security for fine-tuning. In Pakistan, the non-Punjabi front had passed a resolution to explain Pakistan as a “multinational entity”. According to them the three evils of Pakistan are the army, intelligence agencies and the Punjabis. There are 20 million Muhajirs in Pakistan (2004). They are the descendants of the creators of Pakistan. The ethnic divide is between the Punjabis and the rest that comprise the Baluchis, Sindhis, Pashtoons, Seraikis and Muhajirs.⁶⁸

There are many national societies in the world that are too diverse and fractious with huge minority. India is one of them. The United States has its share of almost all the worlds’ people in its society. The ethnic diversity is a reality in every human system. A nation that is not in terms with its ethnicity and get swayed away by perverse belief systems may find it extremely difficult to manage its national security issues.

Box 20.5: What Are Ethnic Phobias?

These are casual terms (non-clinical) used in the media and other open verbal communication sources to explain the aversion a collective group maintains towards another, laced with anxiety, apprehension and fear, all originating from deep-rooted insecurity in the outlook of both—the affector and the

(continued)

⁶⁵Not the legal term based on demographic census. The term minority is legally defined in India for non-Hindus. In the schools in one of the states in India, the term Hindu was dropped in school admission forms and placed as non-minority (would have been majority) as an ethnic detonator widely objected but accepted by people that is termed in this study as acceptance by non-acceptance. Minority communities in India include Parsis, Buddhists, Jains, Christians, Muslims and Sikhs. Minority communities are provided various privileges by the government such as reservations, scholarships and so on in the name of upliftment. This system is relatively exploitable by the powerful and has been continuing for long causing simmering discontentment among people who don’t enjoy such privileges. The term minority is power under the concept of the “the power of one”. This also shows the six religions as explained in this chapter.

⁶⁶Ibid.

⁶⁷Ibid.

⁶⁸Ibid.

Box 20.5 (continued)

affected. It reflects as attitudes in behaviour, sometimes deliberately hidden either by staying way or doing closer. Quite a few ethnic phobias are in circulation that includes the following:

- Xenophobia. Fear of outsiders (outliers).
- Fear of other nationalities such as Anglophobia (English), Indophobia (Indians), Nipponphobia (Japanese), etc. In fact every nationality is phobic of every other nationality.
- Fear of other religions. Christophobia (Christians), Hinduphobia (Hindus), Islamophobia (Islam), Judeophobia (Jews), etc.

Phobias turn out to be stereotypes and antiterms that will induce divisions among humans. It may take time for humans to overcome the ethnic load they create over themselves and rationalise. Till then those in governance should understands such ethnic phobias including anti-sentiments that can limit maximum governance and even turn it around negatively. They can also be exploited by the anteforce.

20.6 Psychology of Hate

Hate is not dislike. It is beyond that emotion. It is a perfect survival emotion that destroys everything around it in a chain reaction. Psychologists make one believe that there is no way out of hate. Hate can seriously harm humans and humanity as a whole. The only solution is to live within hate and manage the consequences by minimising the damage done by it. Human beings cause damage to themselves by hate unseen among other forms of life. Violence, oppression, torture, genocide, terrorism, riots, etc. are only parts of hate-induced activities.

The primitive areas of the brain (the reptilian brain) are said to be responsible for hate. If that is so, why hate is seen more as a symbol of the modern human behaviour? Why the reptiles do not show hate? Why hate is almost absent in the tribals where the emotion is replaced by anger and insecurity of sorts? Hate should be sufficiently modern for humans to identify it and behave as tuned by it as an emotion that recapitulates the primordial instincts in topical manner. Or hate retains the old behaviour that is necessary for existence. In every aspect, hate, as an emotion, may be necessary by some unknown design for survival. Psychologists attribute hate with meaning systems that proliferates any large population.⁶⁹ A fanatical meaning system is considered to be a misguided religious interpretation. Under this principle, an uncontrolled society living on hate can perpetrate unlimited disorder within.

⁶⁹Dozier Jr. R.W. (2003). *Why we hate?* Tata McGraw-Hill Publishing Company. p. 13.

Meaning system is also the belief system of a society. Hate resides there if the belief system is moulded for it.

Coming back in support of sociopsychological authors, hate can be a primitive emotion that measures the flight or fight personalities (avoidance or non-avoidance) for survival and reproduction, the prime directives of evolution.⁷⁰ Flight or fight response is guided by fear, whereas hate is a kind of anger phobia. Phobias are safety mechanisms of the ancient world. They accurately signalled the presence of danger like taste buds learnt to distaste toxic berries. Later, in the advanced human life, precautionary warnings ended up as phobias in the diverse and complicated human mind. In hate, there is negative judgment and permanent registration of design. Ethnic hate lingers under this principle. A person hates another depending upon the prejudice without reasoning that everyone is physiologically identical. That spreads in deeds and activities. If this can be called sick, then the entire human population is sick to the core of their minds.

According to Charles Darwin, hate is an emotion that is more complex than fear, disgust, anger, joy and sadness.⁷¹ Hate surfaces in a society comprising of hate communes where there are people of ethnic diversity that indulge in hate campaigns and meaning systems. Ethnic security needs a special facelift under such circumstances. It is possible by relieving hate from the system by means that are subject to national security maximisation. Hate is a much more complicated emotional behaviour than anger and lingers on for a long period of time, sometimes the entire life span of an individual. Hate is associated with revenge and vindictive behaviour. Stories related to hate is easy for people to get themselves associated with by identifying with the character that spills venom in a mood of vengeance. People find unusual pleasure in acting out hate when opportunity strikes. It strikes every moment in a society where there are divided humans. It is not exactly so when people deal with isolated humans since there is no serious interaction between the divided and isolated humans. Isolated humans like the American Indians were hunted out like wild animals from their properties and disgorged from existence in bloody hate wars.

Terrain boundaries provide claustrophobic scenario for a number of hate groups in the ethnic matrix of a country. Each finds it suffocating to be with another group whom they hate. There are many examples: the Balkans, the Indian subcontinent, Northern Ireland, etc.⁷² Racism-induced claustrophobia within a national boundary was evident in America. Smaller space-limited boundaries can be seen in prison and inner city behaviour.⁷³ The psychology of hate is not the cause of ethnic issue. It applies to it. Hate is an inner feeling that often aims at self in a situation when one feels trapped within oneself. The subject of hate and its influence to ethnic security,

⁷⁰Ibid., p. 15.

⁷¹Ibid., p. 20.

⁷²Ibid., p. 21.

⁷³Ibid., p. 21.

therefore, has to be seen along with other emotions like jealousy, envy, anger, fear, frustration, etc. that controls the human emotional mind in a conditioned manner.⁷⁴

In the dialogue about hate, an important question that often comes up is love considered the opposite of the term. “Let us love, not hate” kind of statements underlines the importance of love in human relations. Mostly people and lexicons will say the term is love. The author disagrees. Love is a fine word for communication but is an abstraction, whereas hate is not (Box 20.6). In other words it is difficult for a government to remove hate from society directly by transplanting love that is abstract. Love, as a term expressing positive emotion, is fine for communication.

Box 20.6: Sir, What’s Love?

Once, a young and gracious girl in the author’s class got up in the middle of a serious lecture. Her name was Sithara Sasidharan. She had a question which the author thought was about the subject he was handling, production management. But it was on a much larger concept. She asked, “Sir what is love in your opinion?” The author thought she would ask on process planning.

Momentarily puzzled the author had another option but to surrender to the innocence of that pretty lady. He shot back in a jiffy, “Well, love is absence of hate; since love is not a survival emotion for humans, it reflects in hate that is a survival emotion, in the absence of it”. He added, “Therefore if one has to love somebody, he or she should have absolute control over all the survival emotions, especially hate and its derivatives”. The author is still exploring, and so he believes also that pretty girl, Sithara.

Hate is the deadliest of the survival emotions. It destroys both—the hater and the hated. No government can eliminate hate, but can contain it quite well. Yes, a government can also incite and whip up hate in the system.

In a normal scenario of ethnic violence, a group of people, who otherwise were perfectly normal, kills the male members. They gang rape women in front of their children before murdering them in cold blood. Babies were thrown into fire in front of their screaming mothers before they were also murdered. And there are the people in the hate-induced human drama charged with the responsibility to enforce law and order under the constitution. They may watch the unfolding scenario of hate merely as spectators. It has happened in many countries and will continue under the law of invariance in the human system. The build-up of hate can take place in any weak moment. It was only a moment in his life for the young Russian, searching for his missing sister in the carnage in Beslan, Russia, where a premeditated attack was made on innocent school staff and children in which about 338 people were killed in September 2004. In his traumatic moment of unsuccessful search, he wailed, “If I see

⁷⁴This conditioning is carried forward from the primitive life and not within one’s life span.

a Chechen or Ingush, I will kill him, or his mother or his son”.⁷⁵ Hate has entered the inner walls of his mind. It will remain there for generations to carry on through mental signatures. One day, many years from now, a Chechen or an Ingush will pay for it without being aware of the carnage in Beslan.⁷⁶ Perhaps the backlash may come from a distant descendent of the man who said, “If I see. . .”. Hate is sown.

20.7 Surviving Jealousy and Envy in an Ethnic Society

Before considering the import of envy and jealousy in the emotional aspect of people in ethnic security matters, it is necessary to understand the difference between the two terms. Both are individual emotions and not societal as an organised behaviour pattern. They are deep-rooted emotions that cannot be easily interpreted. They are different from each other; similarity is in the feelings of negativism. It is the difference that is important in their expressions. For the purpose of this chapter, it may be said that envy makes one feel uneasy at the gain of another that the envious individual cannot achieve, whereas jealousy is the emotion that one feels when another is gifted with gains that the jealous individual has been denied by unfavourable chance. In envy, there is an absence of gain, whereas, in jealousy, there is a loss—both are felt. Though embedded deeply in the individual’s psychological framework, these emotions can be ignited passionately by the perpetrators of violence as it happens in the formation of militia, terror gangs, unions, fanatic antagonists, etc., against those they consider better placed in society. Unlike hate, jealousy and envy do not easily manifest in social uprisings, but contribute to society gradually through individual behaviour patterns. As a hypothesis, it can be said that envy is one of the emotions that make people hate a superpower. This is not tested, though.

Jealousy and envy are important in the study of ethnicity since they can crop up in communities and kindle conflicts among ethnic groups.

20.8 Clash of Cultures

Ethnicity in the sense of national security covers every aspect of divide or isolation between two humans within a nation. It gets a global coverage ideally when the concept is seen either at the level of international security (that strictly is geostrategic

⁷⁵“Russia Mourns Hostage Killings, Questions Mount for Putin.” *Delhi Mid Day*. New Delhi. 5 September 2004, p.11.

⁷⁶Russia better watch out. The situation in Russia’s Muslim-dominated northern provinces is very conducive for break up and further disintegration of the country. The insurgents obviously enjoy support from outside the country.

security—an element of national security) or global security. However, the global approach to ethnicity is still based on culture and the clashes that occur relative to cultural differences. For global security or national security, the world or the nation should be able to absorb culturally diverse societies in its fold as an inclusive society. In the United Nations' perspective, it is an econo-political issue and cannot be achieved without political will.⁷⁷

Clash of cultures in the sense of national security is considered clash of ethnicity in this book. These clashes can occur within oneself or with one and others if one's ethnic liberty is challenged. Ethnic liberty is vital for national security. Ethnic identity is prime. In the multiplicity of ethnic elements, it is the path in search of opportunities in life in equal terms that an individual can achieve. The participation in nation building within the global village is possible only with ethnic identities that an individual is born with. Seldom people achieve this identity in a free mould. Often identities are sacrificed by various themes of discord in society and governance. Privileges meted out by the government to less privileged people take away the opportunity from others and make them shift place to the less privileged. The measures taken to contain ethnic conflicts thus become the cause for new ethnic conflicts. Even in the absence of conflicts simmering discord prevails within the society only to surface at times when patience gets beaten.

Suppression of ethnic identity as part of state policy, directly or indirectly, harms the fabric of governance permanently. The result is furthering economic, political and social discrimination. This makes the suppressed to unite and rise in political identity only to repeat the mistakes of governance that made them to rise in the first place. In ethnic liberty, each individual can identify with a multitude of groups peacefully, and a conflict in one's identity thus mitigates with the support of another identity. In national security, the broadest identity one can get is as a member of a nation, and within this identity it should be possible to make good of the shortcomings if any, in the other distinctive traits of an individual. This way, a top-down approach is possible to reach to the single most identity as an individual in the ethnical mindset. In the reverse, it starts at the bottom with "I am a woman" or "I am a man", to the finding of one's own nationality and finally as a global citizen. Such identification is not an idealist's way of expression or spiritual discourse but a mathematical persuasion of ethnic identity bonding with the self and others.

Ethnic diversity is connected to the ethnic identity of an individual when freed from the clutches of discrimination. Humans are capable of accommodating any number of ethnic diversity, not only with oneself but also with others with whom they co-exist. It is the discrimination that sets in primarily by external behaviour in a group that makes them feel that they are losing their ethnic liberty. If that can be prevented, ethnic liberty will be the most powerful binding force for nation building.

⁷⁷ United Nations Development Programme, Human Development Index 2004 (New Delhi: Oxford University Press, 2004), p. v.

20.9 Ethnic Security—Positive Signals

A positive example of ethnic security under governance can be seen in the state of Mizoram in India. This state in a short span of time has overtaken all other states in India in the well-being of its people. Its standard is not only above the average of India but also comparable with the developed world. The state was in turmoil in the 1980s and 1990s. For two decades, the state reeled under insurgency when the Mizo National Front, a party that was advocating militancy, went underground. It ended in 1986 when New Delhi brought in a peace agreement with them. It was conscious governance balancing with social feelings that had attributed to the success story.⁷⁸ Peace has been the biggest investment. Social development had to be sought with patience. Military enforced patriotism and injected funds from the government may not help to bring peace. Ethnic divides can cause barriers for people. Under such circumstances ethnic insurgence gets popular mandate. Insurgency soon acquires the character of an industry with fervent cash flow and financial networks. People involved or connected with insurgency prosper with fund flow. The security aspects get tightened under the unrelenting forces of money and politics of resistance. The result is a civil society both abused by security personnel and insurgents. Some of the points advocated under this model are to give amnesty to insurgents and avoid the use of military in suppressing them. Local people must have a greater say in their destiny. Here, there is a contradiction in the previously advocated use of force and the current statement of peaceful settlement without the use of force. It is a matter of situational judgment in each case. The previous statement was that a state has sufficient force to quell a riot once it happens. But the underlying principles of ethnic security are to prevent riots and violent activism.

Ethnic security may develop from health security where the third aspect of health security, emotional balance, is duly cared for. No health system in the world today has its concern seriously focused on the emotional balance of its people. Mostly, healthcare means dealing with physical health and limited mental aspects. The importance of emotional balance is yet to be understood by governments and organisations. This has been explained in the chapter on health security. Hate and other negative emotions are within it, and instead of balancing the emotions, they are fanned by inadvertent and sometime very determined indoctrinations that start from childhood in a society. This is where the governments have to strike if the objective is national security maximisation.

⁷⁸“Editorial, Mizoram Model” *The Times of India*, Mumbai. 16 August 2004, p. 12.

20.10 Ethnic Security—Negative Signals

A few incidents of positive signals are collector's items in ethnic security. They are rare. Whereas the vibes are generally negative in a human system. One can feel it almost daily. What tops it all is a reported ridicule by a radio station in the world's oldest electoral democracy—the United States. A popular New York radio station was reportedly aired a song with following lyrics ridiculing the 2004 tsunami deaths in Asia and Africa:⁷⁹

*There was a time, when the
Sun was shining bright
So I went down to the beach
To catch me a tan.
Here, the next thing I knew,
A wave of 20-feet high,
Came and washed your whole country away.
And all at once, you can,
Hear the screaming chinks.
And no one was saved from,
The waves.
There were Africans drowning,
Little Chinamen swept away.
You can hear God laughing.
"swim you bitches swim".
[Chorus]
so now you are screwed. It's
The tsunami.
You better run and kiss your
A** away.
Go find your mommy.
Just saw her float by,
A tree,
Went through her head.
And now your children will be,
Sold into slavery.*

The radio station (name withheld) reportedly regretted airing the song when they received many protests.⁸⁰ Well, that is it when ridicule rules the roost in a world of hate where ratchets annealed in insecurity are out in the open. They may strike any time. There are more to negative ethnic security as and when the world advances.

⁷⁹“Agencies, Global Outrages as US Radio Ridicules Tsunami's Victims.” *Mid Day*, Mumbai. 27 January 2005, pp. 1, 7.

⁸⁰Ibid.

Human systems can even retard with time under fear and hate and go on the reverse. It is evident in the reported treatment of the dead in Kerala, in India, where ostracism of AIDS patients had gone to the extent that the bodies of the dead were unwelcomed in the Catholic Church's cemetery grounds. They did not get the last rites by the priests. Such prejudices of ethnicity in death are a matter of dismay according to an editorial in the *Hindustan Times*.⁸¹ Bodies of such victims were cremated against the Catholic belief systems. Does ethnicity follow humans even beyond their graves? It does.

20.11 So, What Is Ethnic Security?

Ethnic security, in this study, is the 12th element of national security in the chronological hierarchy of the 16 elements. Ethnic security, "ethnicsec" in short with the allotted symbol "e_{s3}", is about the well-being of all the people of a country sans any ethnic differentials where ethnic differential is the degree of difference between one individual human and another which under ethnic security consideration can be from the perspective of belief systems, gender, sex, age, location and any other parameter in which one individual attempts to stand separate from the other rather than the original and standard personality traits that will be common as a human at any given time.

20.11.1 Definition—Ethnic Security

Against the background of this study, ethnic security means *the capability of a nation to consider and govern every individual human that comprise the population of that nation on equity and equitable basis without prejudice or attributing any ethnic differences as identified and defined in this study, perfectly aligned with the other elements of national security and integrated with all the terrains of national governance.*

20.12 Summation

Ethnic security, in its early form, was brought to the forefront from the varying belief systems of the limited religions of the world. Every religion believed that it was better than the other and desired to be the only one. It happened in the mad race for survival. In ethnic gambles controlled by belief systems, the power of insecurity cordons off logical thinking when threatened. Mostly these threats are internal to a human being. Human thinking and behaviour become irrational when security is

⁸¹"Forsaken Sheep." Editorial, *Hindustan Times*, New Delhi. 29 April 2005, p. 10.

threatened, though momentarily and sometimes permanently such thinking is considered to be sagacious and rational. This can be seen in every action of a human being under threatened security. The power of insecurity can throw logical thinking into bottomless pits (Leoni's well explained earlier) at any moment. It is important for human survival from primitive days. It may take ages to get over such behaviour.

Ethnicity under the element of national security is beyond religious separation. In ethnic security analysis, everything that determines a person different from another and the concurrent differential attitude towards the other person based on that difference is taken into consideration. It is not separation based on religious beliefs alone. Irrespective of nearly 8 billion plus people in the world, still increasing, it is noteworthy for strategic analysis that there are only a few major religious beliefs that can be counted on the one hand: Zoroastrianism, Jainism, Buddhism, Christianity, Islam and Sikhism in that order.⁸² The timeline is relative to Christianity, the middle one between BC (before Christ) and AD (Anno Domini, Latin for "in the year of the Lord"). It is not a kind of universal time, the first day starting with the "birth" of the first human biped. Hence, everything in time-life becomes relative to the system entropy for timelining. If one takes away the six religious cultures, the remainders are the natural people who are yet to convert or change from their original culture, though they consider their cultures as their religions in the security application. All cultural religions are strictly one in basic character and tenet, but in different names and nature based on geolocations. Religious cultures spread beyond their original geolocations. Every religion has subsystems of the basic belief systems in differing shades.

The formation of cultural religion started with the first biped bringing in god to help him or her (most probably her⁸³) to hang on. But this study takes religious cultures originated from cultural religions beginning with Zoroastrianism considered to be in the sixth century BC. The same century seemingly brought another two—Jainism and Buddhism. Perhaps the century had something to do with human intellectual appreciation about the self and surroundings. It would have been caused by violent and aggressive survival behaviour. Every modification would have had purpose behind. The last religious culture, Sikhism, originated in the sixteenth century. The accuracy of this statement is not important here as this study is about governance and ethnic security.

Considering this was the way of things, then the human transformation from cultural religions (original people) to religious cultures (modified people) happened

⁸²Zoroastrianism (sixth century BCE), Jainism (sixth century BCE), Buddhism (sixth century BC after Jainism), Christianity (first century AD), Islam (seventh century AD) and Sikhism (sixteenth century AD) are considered by this study as the human religious cultures and the rest as collectively cultural religions. All these religions have subreligions and tributaries. But the fact is that there was no more similar formation of human systems based on the concept of god in three forms. The formations of such societies subsequently became political and similar ideologies such as communism. The world has governed beyond the formation of new and different religious cultures modified from the original.

⁸³Not elaborated here.

in six steps in a period of about 2100 years: sixth century BC to sixteenth century AD. Thereafter it took a different turn in cultural transformations with the advent of more definitive and violence driven sociopolitical systems. But the fact is that all belonged to human behaviour of the period and came out through violent clashes within the unitary civilisation. These statements are only for academic interests to appreciate ethnicity to the extent that it is not about religion or any specific differences but all differences as perceived by humans. Religious separation is seemingly stronger than all other severances. Hence the model for governance is unitary—that it is about the comparative behaviour of people in society where they cannot remain insular. In such case humans have to identify themselves differently from another cuing in ethnicity. This mindset is what the government has to handle in governing ethnic security and provide for the well-being of people. Yes, it is not a difficult task if the governments do not play the game of ethnicity.

It will be hard for another religion to come by in the future because the world has changed and is constantly moving ahead. What one may see in the future is not the subject of this book, though it can be discussed. The readers who accept these facts may be able to visualise looking into the future. The bottom line is that ethnic security is not seriously about religion and religious difference. It is about all differences. It is the social difference attributable to a person and the disharmony associated within a group that causes problems for the overall well-being of an individual with the system. It could happen for many reasons and not by religious beliefs alone. Religion should not have to be a problem for humanity. It is strictly individualistic for overcoming the built in insecurity. It is a necessity for now and long.

An interesting observation is that mostly in a form of ethnic violence, the victims are different from the identified enemy. The enemy is not the individual victim, but the hidden objective cause. The victims are only identified as the shadow enemy to affect the interaction for the cause with the enemy. It is the punching bag syndrome. The rage reflects on the bag. The humans cannot change that soon in a small time universe where a “small time” could even be thousands of human generations. Humans are neither made to observe change when it happens or to change themselves or the world at a pace that is faster than what is designed by default.

Projecting humans as peace-loving creations is one of the highly intransigent myths. Human race will be choked to extinction in a world free from violence. Violence is the key. The system is designed that way. Suicide rates increase when everything is fine. Violence cuts down suicide. It is an accepted and tested hypothesis. Peace is an abstraction. It is an impossible dream. It never happens. In fact no one has ever seen or experienced the strange entity—peace. It is like the mythical *yeti*—the abominable snowman of the Himalayas.

No country is free from ethnic issues in the world today. It is always simmering at the edge everywhere. A country can be secular (another abstraction that is not unreal) by constitution. It does not mean the people are secular. Secularism in such cases is constitutional aspiration. In a secular society, the communities will resent appeasement of a particular section of people. That may cost elections. More than that, such resentment may brand the community non-secular, whereas in the strict sense, the

community resents appeasement because it is secular. They will resent appeasement of the minorities as well as that of the majority.⁸⁴

At the end of all these discussions, the study falls into a “perfect” dilemma of sorts which nullifies the original lemma on which the study reflects: humans are cooperative species. How can humans be a cooperative species if they get on each other’s way in the name of survival? That is a question for the intellect that humans are supposed to possess as their survival tool. Is it a predicament? It cannot be, even if it sounds one. Humans need humans. But the way nature desires for human species to survive is a bit different in the overall design. There is certain strict “no-noes” in the book of nature. There could be reasons for it if looked along the reverse tack. It is simple, if one can take away the cooperative term and avoid the semantic dissonance in the system. Humans are simply interactive species and not cooperative as the term commonly meant to be. Cooperative means helping each other. The energy for human survival lies in the interactive matrix of people where cooperation is sought. Interactiveness supports nature’s cause of life. Conflict and cooperation as relative expressions are parts of the interactive matrix. That means the participants in interactive behaviour need support external to them to balance the forces of survival. This support has to come from the government through governance. That is why anarchy can turn dangerously destructive. Because anarchy is sans government. Anarchic form of governance cannot provide the external force to balance the interactive survival. It can lead the system to chaos. The idea of ethnic security is more in preventing the entry of anarchy in governance. It needs governing ethnic security by the government to balance the interactive matrix which will be contrasted by cooperation and conflict. Conflict in a human system, therefore, is as natural and acceptable as cooperation being human species is interactive. It is governance that matters and is required.

The idea of ethnicity can be very complex, controversial and fast-changing based on the element that makes it ethnic. In fact every human is a multi-ethnic person in the study of ethnic security. There is no single ethnic or non-ethnic human. Every aspect of ethnic difference needs serious attention of the governments. Every human is ultimately the same and similar by singularity in differentiability.

21.1 Introduction

The Earth is the only living planet in the solar system. The reason is its life-supporting environment. Environment is anything that surrounds and influences a thing or an entity. Environment is relative to the thing or entity. Care for the environment for humans is all about sustaining life and themselves. The other life forms are inclusive of human environment on the planet. Any damage to the environment can impact life and its survival on the planet. It's that simple.

One of the definitions of environment is that it is the aggregate of all external conditions and influences affecting life and development of organisms.¹ It is an ideal definition for this study. The responsible world is aware of the effects of environment on the survival of life on the planet. There is focused attention on major environmental issues like global warming, land degradation, ocean pollution, deforestation, acid rain, depletion of the protective ozone layer, space debris and so on. Environmental issues that the world faces today can have serious effect on future generations to come. Since the environment influences and shapes human life in many ways, environmental security is considered an element of national security. Environmental influence is transnational, though localised issues are far too common and collectively contribute to the global environment. Serious issues cannot be contained between the borderlines or areas of a nation. The repercussions of environment are worldwide. Being transnational, the threat to environment is to be appreciated at global level while assessing factors related to environmental security.

Environment is exceedingly related to resource, health, demographic, geostrategic and disaster security elements within the national security paradigm. This is besides the impact it has on other elements of national security. In the global outlook, the issues when broadly placed can be identified as those like global warming, El Niño, forest fires, ocean degradation, military operations, etc. that can peter out the quality of life of the inhabitants of an affected state or a region. When localised, the issues are those that affect the territorial integrity or political stability of a nation such as disputes over scarce water resources or rehabilitation of hapless refugees fleeing a degraded environment in search of a better life.² There are many such environmental refugees in the world. More are created every day. For these reasons, environmental security has to be seen in a global perspective along with its national attributes. The magnitude of the problems related to environmental security and associated issues in the world today are far-fetched.

21.2 Environmental Security—Setting

Environment, in its natural state, has its complex physical, chemical and biotic factors that act upon an organism or an ecological community and ultimately determine its form and survival.³ Whatever life consumes has to come from the environment. Environmental security relies more in the protection and preservation of the environment to make it potent for sustainable development and survival of life on Earth than on response activities. It involves sustainable development of environment and protecting national wealth linked with ecosystems, resources, terrain advantage, energy systems and all forms of life in the biodiverse plain. Currently, environmental security is sagaciously applicable to the four geophysical terrains—land, ocean, air space and contiguous space. It is yet to extend seriously to the non-geographical, though physical, outer space. There are already concerns of contiguous space becoming an overhead (Albert Einstein may not favour the overhead expression, though) junkyard of space vehicles, burnt out rockets, slipped off screwdrivers and other knick-knacks. It may be a short gap before the world communities seriously take note of clean contiguous space of the planet they live. The contiguous space is the conduit through which the Earth gets blasted every moment with harmful radiation from outer space. The ozone layer at the outer border of air space acts as an armour, protecting the planet from harmful rays. It is reported that the ozone layer is pierced by ozone-depleting gases, creating a hole over the South Pole in Antarctica. The hole though periodically gets narrowed down is expected to close permanently one day. There was also an Arctic hole which is now closed. The report of the ozone holes caused alarm among the world environment watchers. The Antarctica hole occurs annually and reportedly spread out to 24 million square kilometre in October 2020. It was observed closed according to the World Meteorological Organisation (WMO) in January 2021. The WMO has been monitoring the ozone hole since first reported in 1985.⁴ There is good news and bad news in this finding. The bad news is that if it can heal, it can also resurface another day if the causes persist. The good news is that the environment can heal itself to a great extent under the power of the planet. The environment protects life. That's the bottom line of environmental security.

³Encyclopaedia Britannica, Ultimate Reference Suite, DVD, 2004.

⁴According to the World Meteorological Organization (WMO). 6 January 2021. "Antarctic ozone hole—one of the largest, deepest—closes." Down to Earth. <https://www.downtoearth.org.in/news/climate-change/antarctic-ozone-hole-one-of-the-largest-deepest-closes-74943>. Accessed 14 February 2021.

21.3 Challenges to Environmental Security

Various human activities challenge environmental security in the physical terrains. Ironically some of them originate from activities meant to improve the quality of human life.⁵ Some of them are from unlawful activities. Yet another is related to military operations. The stress and strain on the environment is continuous and ever-increasing. The factors that contribute towards them are many. The identified causes are as follows:

1. Population growth
2. Developmental projects
3. Resource usage
4. Terrain abuse
5. Incidents of disaster
6. War and military preparations
7. Militant activities
8. Unlawful activities
9. Hazardous and toxic materials
10. Legislation and enforcement
11. Global warming
12. Climate change
13. Genetic modification
14. Waste management
15. Biodiversity depletion

Every one of these factors is equally important from the perspective of environment. There are more. It is difficult to say which is more important. It depends on situational changes and sense of urgency. It is for the national governments and international agencies to decide. The activities associated with these factors and their effects to the geographical terrains are far too many. The effects are Earth degradation, water pollution, air pollution, marine pollution, biodiversity depletion, waste production, resource depletion, energy depletion, food supply breakdown, health problems, acid rain, disaster probabilities, etc. Worst are the collateral damages that follow.

They are further examined in subsections.

⁵It is an interesting paradox of existence that what is meant to support a system, in turn and sometimes in the long run, uproots it. The consequential changes are to blame for this turnaround in any effort or activity. This is an interesting subject and is the basis of chaos theory.

21.3.1 Population Growth and Environment

Population growth was mentioned in the chapter on demographic security (Chap. 13). The combined population of the world is growing fortuitously, and the trend is expected to remain so, even though there is a decline in some parts of the world.⁶ The population growth induces pressure on the environment, thereby making the policies and measures inadequate for its protection and regenerative preservation. The growth of population is naturally a cause for alarm as it may tend to cause an environmental catastrophe eventually. There is a different school of thought advocating that population, if controlled and made supportive, is good for a nation. It is based on the concept that people are the most precious investment instruments in national security. Everything a government does for NS_{max} is ideally for its people. It has to be executed through them. National security is a people-centred concept. It is people who propel social progress, create wealth and advance science and technology that transform human systems into a better world. The environment can be used for this purpose in a sustainable manner. It can only be done through people. While finding an opportunity in the growth of population is a seriously debatable matter, an oversized population undoubtedly increases demand for resources including energy that may be in limited supply. Regenerative resources may be wiped out by consumption faster than their capacity to replicate. Under uncontrolled and poorly managed situations, population can prove a curse to the environment, which in turn will affect their survival. Overexploitation, land degradation, energy and resource crunch, health issues, etc. will be recurrent. But population can be a boon if managed effectively for positive contribution. It is a difficult task that is not yet tried out successfully in governance.

21.3.2 Developmental Projects

Developmental activities often encroach into sustainable and life-supporting environmental areas. The result will be the destruction of such habitats that in turn will affect human existence. The use of land is a key issue. It is directly linked with resource security and disaster security. It could equally affect the ocean environment when developmental activities over the maritime zones invite problems, if not effectively regulated. Developmental activities will further cause pollution, acid rain, ozone depletion, greenhouse effect, water pollution, deforestation, etc. The health and integrity of natural resources will decline to the tipping level. A quarter of all mammal species are threatened, which the World Conservation Union estimates, and a key reason is that humans continually encroach into their habitats, both on land

⁶The world population is growing approximately 74 million per year. “Population and government: a global challenge.” Australian academy of science. <https://www.science.org.au/curious/earth-environment/population-environment>. Accessed 18 January 2020.

and water. The interplay between habitat destruction and wildlife is a very important matter for ecosystem management.

Global governments need to understand and appreciate the relation between environment and successful economic development. While development is generally localised, environment is global. The impact of developmental activities in one location will have the effect globally. Identification and assessment of environmental development impacts of developmental activities are carried out formally in various countries. They are very limited as majority projects are carried out recklessly sans responsible environmental concern. There are many variants of impacts which may be caused by anthropogenic activities on environmental and social systems.

21.3.3 Resource Usage

Resource management is a correlated function. Over consumption, exploitation and wastage of resources can leave a telltale effect on the environment permanently. Energy resources, if overexploited or wasted, can plunge the future into absolute darkness. It is also important to understand that when it is a matter of environmentally sound strategy, in certain cases, especially in energy and developmental project management, it has to be “environmentally safe and sound”. Resource management in relation to environment also extends to mutual balancing of trade and environment. Resource security is closely interrelated to environmental security. Natural resources exploitation, exploration, mining and processing have caused different types of environmental damages which include ecological disturbances, destruction of natural flora and fauna, pollution of air, water and land, instability of soil and rock masses, landscape degradation, desertification and global warming.⁷

21.3.4 Terrain Abuse

Environmental security is not only land-based but also extends to other geophysical terrains: ocean, air space and contiguous space. Terrain abuse is far too common over land, air and ocean. Though too early to understand the environmental impact, space operations has been polluting the contiguous spatial area with debris that is hazardous to land, air and ocean. The contiguous space too will be an area where solid pollution can become alarming if not regulated.

⁷Babagana, G., Aji, A.M.M., and Garba, M. “Environmental impact of natural resources exploitation in Nigeria and the way forward.” 01 January 20212. https://www.researchgate.net/publication/265102234_environmental_impact_of_natural_resources_exploitation_in_nigeria_and_the_way_forward. Accessed 8 May 2020.

The pollutants generated in one terrain can shift to another. Unless eliminated totally, a pollutant originated in one terrain can get transported to another terrain or another area within the terrain itself through transboundary leaching or discharge. They will remain trapped if not free to move for prolonged periods. An example is Pangong Tso or Pangong lake at the highest attitude in the Himalayas is polluted. The lake, according to the author, is a sea (Pangong Sea, more realistically Pangong Sagar), alike the oceans down below at sea level though in varying elevations over the planet (Box 21.1). Tourism in the Himalayas is the main cause for the pollution of Pangong Tso.

The international community, who is aware, is concerned about the dangers of terrain abuse. The national governments are also generally serious about it.

Box 21.1: Pangong Tso Is Not a Tso

Tso means lake in Tibetan language. There is no singular word for ocean in Tibetan. The word gyal-tso meaning large lake or victorious lake may mean ocean. It also means wisdom in common usage. Hence it was obvious the people of Tibet didn't have to find a word for ocean as they were never privy to the Tethys Sea that lapped their shores millions of years before and even when the Indian plate collided with the Eurasian Plate, creating the Himalayas and emptying Tethys Sea almost completely forming the Indian Ocean. Pangong Tso today is the last sign of Tethys Sea—a souvenir to keep. Tibet became landlocked since the collision and settlement thereafter. But there is still the push movement. Pangong Tso has all the characteristics of a sea including salinity. The pH value of the water is more than the ocean or any lake or river at high altitudes. In Greek mythology Tethys is the mother of Proteus and wife of her Titan brother Oceanus and mother of many sons including Proteus mentioned elsewhere in this book. The collision lifted up the Pangong Sea to the mountain top at an altitude of about 13,000 feet. The animal fossils available in Himalayas show it was formed by the collision of the continents over the Tethys Sea. According to this study, Pangong lake qualifies to be called a sea and should be named a sea instead of a lake as in many landlocked parts of the world. It belongs to China and India today as Tibet is no more an independent geontology. Hence the appropriate name should have been Pangong Sagar. Pangong in Chinese means boomerang and sagar in Sanskrit means sea. Considering it is a disputed territory between China and India, the change of name will not only geographically and geomorphologically accurate but also under international law if wisdom prevails among the advancing sapiens to consider resolution under maritime law as historical waters one day. The water of Pangong Tso is much beyond history in time; it is mythical.

21.3.5 *Incidents of Disaster*

Incidents of disaster (INCDIS) cause loss of life, property and environment which together or independently is termed a disaster. The incident per say is not a disaster. It has been mentioned in the discussions on disaster security, the sixth element of national security. INCDIS, also termed disaster incident, may cause collateral incidents of disaster. All these together can cause havoc in the environment for long durations. It is therefore necessary to analyse the damages to the environment with respect to a particular disaster incident. Environment is a healthy breeding ground for collateral damages, some of them more destructive than the original incident. These secondary problems, like a tsunami in the case of an earthquake in an island, can spread the damage to a wider area.

Disasters jeopardise all measures of environmental security. Disaster prevention is always a better method wherever possible than mitigation by response. It protects the environment from sustaining damage. While a disaster-free world is hard to imagine, the beginning of a solution for environmental security is based on the principles of zero disaster policies.

An example of an incident of disaster causing environmental damage is the nuclear burn out on 25 April 1986 in Chernobyl in the former Soviet Union. The power station, situated at the settlement of Pryp'yat, north of Kiev, in Ukraine, had four reactors capable of producing 1000 MW of electric power each. The prime cause was human error. The core melted down partially. The chain reaction in the core went out of control resulting in several explosions that spew large amounts of radioactive material into the atmosphere that spread out to a vast area. The radioactivity spread by the wind over Belarus, Russia and Ukraine and soon reached as far west as France and Italy. Millions of acres of forest and farmland were contaminated; lives stocks were born deformed for many years.⁸ There was an international outcry over the incident and dangers posed by the radioactive emissions. According to estimates, 50 to 185 million Curies of radionuclides escaped into the atmosphere. The radiation was several times more than that caused by the nuclear bombs in Hiroshima and Nagasaki during the Second World War. Dozens of people died and many contracted serious radiation sickness that killed them subsequently. Such casualties are bound to happen anywhere anytime when human slackness overpowers caution. One such incident, though in much smaller scale, was the Bhopal gas tragedy in India when toxic gases were released in the environment allegedly by human error.

⁸Encyclopaedia Britannica, Ultimate Reference Suite, DVD, 2004.

21.3.6 *War and Military Preparations*

An agenda that is not seriously reviewed by the world environmental agencies, even in international forums, is the damages that war and military preparations can cause to the environment. Such damages are not strange issues. It has an ancient beginning when the Romans destroyed the fields of Carthage by spreading them with salt. In the modern world, the United States experimented with chemical weapons and climate modifications in the prolonged Vietnam War causing heavy damage to environment. The use of napalm bombs to burn forests and Agent Orange to defoliate the trees and seeding the clouds under Operation Popeye over the terrain to induce floods is the amateurish, though looking scientific, and panic-driven environmental warfare techniques that are quite seriously etched in the archival memories of Vietnam War.⁹ In the Persian Gulf War of 1991, the retreating forces of Saddam Hussein intentionally set fire to oil wells causing unprecedented air pollution. According to reports, 780 wells were set ablaze.¹⁰ Subsequently, the Iraqi forces pumped out about 30 million barrels of oil into the Gulf.¹¹ It was huge, about 30 times larger than one of the large accidental spillage—the Exxon Valdez oil spill near the shores of Alaska.¹² The slick expanded over 600 square miles in the Persian Gulf and fouled 640 kilometres of coastline. Marine life was devastated. More than 20,000 shorebirds perished. The response activities were delayed and met with impediments, because of the continuing war, inaccessibility for response vessels and quicksands dangerous for human approach.

The interest in environmental damages to national security also comes from the fear of a prolonged nuclear winter that the world may face in the aftermath of a nuclear war. In a large-scale nuclear war, the resulting smoke and dust can radically alter the climate conditions of the Earth. The Environmental Modification Convention of 1977 forbids the hostile use of environmental modification techniques having widespread, long-lasting or severe effects as the means of destruction, damage or injury to any other state party. Environmental modification technique is defined as any technique for changing, through deliberate manipulation of natural processes; the dynamics; composition or structure of the Earth, including its biota, lithosphere, hydrosphere and atmosphere; or of the outer space.

Environment suffers when state falsely considers military security is the ultimate bidder for national security. Concern over environment is pushed behind. The

⁹The outcome of environmental war in Vietnam was the Environmental Modification Convention (ENMOD) and Protocol I to the Geneva Convention. ENMOD was drafted in 1976 (came into force in 1978) to prevent deliberate manipulation of natural forces during times of war.

¹⁰Paleri. P. (1994). "Environment As a Weapon of War." Point paper for academic requirement." (Unpublished). National Defense University, Washington, D.C.

¹¹Ibid. However it is not clear whether the intention of the Iraqi forces was to deny oil to the enemy or to pollute the environment as a weapon of war. Probably the reason would have been the former as subsequent events show that the targeted objective could be causing energy crunch, not environmental chaos. Or it could simply be an act of denying booty to the aggressor.

¹²Ibid.

consequences are disastrous under such policy statements. Military operations other than war that deal with preparedness of the forces can cause instant and collateral damages to the environment. These will include large-scale military manoeuvres and advanced weapon testing including weapons of mass destruction. Environmental consciousness in such military operations are gaining ground slowly in recent times, though it is highly restricted to nations that have advanced facilities to carry out exercises and tests without causing harm to the environment.

A subject that has been gaining ground seriously is the role of the military in environmental security. Military forces, historically, have a notorious record of damaging the environment. These damages were in some cases deliberate. Vandalism by the forces during war is much talked about. Environmental damage not only takes place in war but also in daily military operations and exercises. The situation is changing with better appreciation of the environment. International conventions do not hold much value unless the warring nations are party to them. The gap between *de jure* proclamations of policy and *de facto* compliance of military forces in adhering to them can be wide.

There are apprehensions about saboteurs and terrorists holding environment hostage, threatening to cause serious harm to it. The world has to be prepared for any such eventuality.

21.3.7 Militant Activities

Militant activism is primarily destructive. Militants are combative and aggressive. Militancy is one of the behaviour patterns within the human system leading to rebellion and anarchy. Militants are not concerned about the environment or value systems. They focus on perceived cause for their livelihood; the latter is more important. The cause is for livelihood for militants, hence secondary even for non-militant humans in most cases. Militants would demand destruction of the existing system to transform or to meet a demand. It is the known objective of militant activities. They feel weaker than the state, especially the government that represents it. They resort to destructive acts most of the time. It is the proof that they are weak. In the process they can seriously damage the environment. Various militant activities in the world include terrorism, Naxalism, Maoism, insurgent activities, support to crimes and so on. All these cause damage to natural environment by exploitation.

21.3.8 Unlawful Activities

Besides an act of militancy, there are many unlawful activities that damage natural environment—polluting; land grabbing; converting agricultural land into construction land; filling up natural reservoirs; sand mining; quarrying; waste trading; space

pollution; usage of non-biodegradable products; environmental crimes such as illegal trade in wildlife, illegal logging, smuggling of ozone-depleting substances (ODS), illegal, unregulated and unreported (IUU) fishing and so on. Interestingly the physical environment can influence unlawful activities such as drug farming and refining, insurgency refuge and so on. They affect potential offenders' perceptions about unlawful activities providing protective crime sites.

21.3.9 Hazardous and Toxic Materials

The developing world has an additional problem in hand—hazardous and toxic materials including wastes. Production, trade, use, transportation and disposal of hazardous and toxic materials are serious threat to human health and environment. Safe handling of these materials is a major concern of governments and international organisations.

21.3.10 Legislation and Enforcement

Legislation and enforcement are critical factors in protecting the environment. This calls for stringent laws without affecting the normal “traffic and business” at national and international level. Such laws will also need the backup enforcement that includes a quick delivering judicial system. There are many protocols under international law including those related to laws of war. More are in the making at various stages. At the same time, many nations have problems with national legislations, effective employment of enforcement agencies and associated issues. The laws related to environment need not be exclusive to environment. Environmental damages can be regulated through various other laws and regulations in vogue.

21.3.11 Global Warming

Global warming is the most discussed environmental topic today for reasons that are obvious. Global warming is considered as one of the major issues that may affect environmental security. The starting point was the alarm caused by the discovery of a hole in the ozone layer over Antarctica in 1985. It was the first unmistakable sign of human-induced change to global environment. Chlorofluorocarbons are the principal cause of ozone depletion. The 10 hottest years of the century have all occurred since 1973. Out of which the 1980s saw seven of them. Public awareness of climate change became particularly acute in 1988. The greenhouse effect was said to be responsible for this warming trend. It was a year of heat waves, fires, floods, drought and super hurricanes. Author Paul Brown paints a grim picture of the scenario in his

book on global warming.¹³ According to him human-induced global warming is a fact. Large parts of the civilised world may not survive if global warming is not arrested. The small coastal and island nations are likely to disappear below the rising sea when the ice caps melt.¹⁴

For more than a century, people relied on fossil fuels such as oil, coal and gas for their energy needs. The consequences of this are global warming as it is found out.¹⁵ Global warming caused by burning of fossil fuels is the worst environmental problem the world is facing today according to environmentalists.¹⁶ They recommend alternative sources like wind power, solar energy, tidal energy, etc., as more appropriate choices. The United Nations' Intergovernmental Panel on Change (UNIPCC) presents a gloomy scenario about the steady intensification of global warming for the tropical and developing countries. The panel talks about storms and rising sea levels. James A. McCarthy, an environmental scientist based in Harvard University, predicts that most of the Earth's people will be on the losing side.¹⁷ Stabilisation of the greenhouse gas concentration spelt in the "Treaty of United Nations Framework Convention of 1994" to which 165 countries are signatories may yield a solution.

Global warming is a hot issue in discussions and debates. There are movies on it besides campaigns for and against. Movies make it look figments of imagination, but the debates, when hot, picture a scenario of impending doom. It was also told that global warming is nothing new, but a cyclic process in which the world gets hot and cold periodically since it is not yet settled down. The North Pole was warm; it was stated, during the prehistoric period due to global warming.¹⁸ Volcanoes spew up all kind of gasses once a while that is equivalent to many years of industrial outlets of such gasses. According to studies, global warming churns up weather disasters that kill around 123,000 people a year.¹⁹ Heat waves in various parts of the world are attributed to global warming.

In the pre-industrial era, the level of carbon dioxide per cubic metre was roughly 278 ppm. Today it is 376, the highest in 4,20,000 years or so.²⁰ This means the air today is more polluted than it was before. If the current rate of carbon dioxide accumulation continues, on a linear scale, the temperature by the end of the century should rise by 6 °C according to the UNIPCC. Global warming may cause food insecurity, increasing the number of hungry people to 90 million in this century.²¹

Obvious side effect is health insecurity. The carbon increase in the atmosphere is caused by burning what was lying underground for millions of years as fossils. Global warming itself will increase the carbon content by reverse process, because the oceans and plants will lose their ability to soak up carbon. Invariably, the rain forest ecosystem will collapse. Each time a tree collapses, stored carbon is released. This is in addition to human release by fossil fuel burning. Changes will be noticeable by the middle of the twenty-first century. But the humans are capable of slowing down this process. This requires improving energy efficiency.

The effects of global warming on the environment today are varied. The world certainly is warmer than before. Infectious diseases are increasing and shifting ranges. Sea level rose by four to 10 inches in the last century, causing destruction of beaches and wetlands around the world because of melting glaciers and snow covers in five continents. More than 5400 sq miles area have broken off the Antarctic ice shelves and melted. There are drastic habitat shifts of plants and animals. Migratory behaviours of animals have been noticeably altered. Species that are unable to adapt to the changes are vanishing. There are also more frequent storms and surges and unusual weather phenomena noticeable around the world. There are surprises too from nature. Some of the presumed extinct species have been relocated.²²

The pressure points, according to a report in the *Guardian*, where the effect of global warming will be highly amplified and serious enough to cause conceivable damage to the world are about a dozen.²³ The scientifically identified fragile systems belong to the Sahara Desert, the Amazon, the Siberian ice sheets, the Green Land ice sheets, the North Atlantic Current, the Atlantic circumpolar current, the monsoon, the Tibetan Plateau, the saline valves of the oceans, the ozone hole, El Niño and the West Antarctic Ice sheets.²⁴ To understand the impact the global warming has on them and the world as a whole corollary to such impacts, one has to understand that they are not just fragile systems but also sensitive balancers of environment as it is today. Some prefer to call them the tipping points.²⁵ A small change in their current form of existence can cause sudden and catastrophic changes in the world environment. According to report, the Sahara may face rain and shrink in its area. The fertile planes will be a boon for some, but will be disastrous for the overall planet's health. The fertility of Atlantic Ocean nearby comes from the nutrients that are lifted up with sand from the Sahara. Once they are lost, the Atlantic will be infertile. As the Sahara

²²“Beasts Back from the Dead.” *Hindustan Times*, New Delhi. 15 May 2005. p. 18. According to reports there have been recent natural discoveries of new species being found or life forms long held to be extinct being rediscovered. Among the new are the Laotian rock rats, an entirely new family of wildlife, and pigmy goby, a new fish species in the Great Barrier Reef. Among those rediscovered from their long believed extinction are Wollemi pine trees in Australia and the ivory-billed woodpecker located in the backwaters of Arkansas, United States. More such discoveries are expected showing signs that the world will have many positive surprises in store to the hopeful.

²³Sample, I. “Pressure Points.” *The Guardian G2*, 14 October 2004. pp. 4–6.

²⁴*Ibid.*

²⁵*Ibid.*, p. 4.

becomes green, the Atlantic will die off without planktons that will die in the absence of nutrients. The chain reaction will extend to fishery resources that depend on plankton. Massive ocean fertilisation will be required, and the world does not have the expertise yet to do it safely. The food chain collapses. That is not all; according to the report, the sand from the Sahara controls the formation of cyclones in the Atlantic. Once the cyclones originate, there will be disaster awaiting the Atlantic coastal areas. The wetlands of the Sahara will breed locusts that will invade across the border and attack crops in Sudan, Algeria and Morocco.²⁶

The Amazon contains the most diverse ecosystem in the world. It is based entirely on the rainfall. Global warming can cause a drop in rainfall. That means death to the forest that will liberate stored carbon dioxide into the atmosphere accelerating global warming. Species and ecosystems will perish. Siberia is another tipping point. The icy oceans of Siberia hold large quantities of methane clathrates. A clathrate is a gas-filled ice. About 10 to 11 trillion tonnes of carbon are locked up in clathrates in the Siberian ice. When the ice melts by global warming, the gas will be released into the oceans and the air space. Methane is a strong greenhouse gas that is toxic to many species.²⁷

The Greenland ice sheets contain approximately 6% of the world's total supply of freshwater. If it melts, the North Atlantic Ocean will not only rise in level but also decrease in salinity. It will happen if the current temperature goes up by 3 °C. If it is up by 8°, the Greenland ice will disappear totally. According to scientists, it will take 60,000 years to revert back.²⁸ That is a long time for the humans, though negligible on the cosmic scale.

The ocean is a living entity and the currents are their lifelines. The North Atlantic Current alone brings to Europe the equivalent of 100,000 large power stations worth of free heating. When the sea dilutes by rain and freshwater, the North Atlantic Current will change in its pattern. This had happened about seven times in the last 50,000 years according to historical studies.²⁹ The countries that will be hit will be Iceland, Norway and Scotland. Another ocean current is the Atlantic circumpolar current. It churns around 140 million cubic metre of water around the Atlantic every second, mixing water from the Pacific, Atlantic and Indian Ocean and transporting nutrients around from dead plankton and other marine life.³⁰ A change in its pattern by admixture of freshwater from melting ice can cause serious problems.

The monsoon is the food line of India. If India is heated, the monsoon will drop. The result will be heat wave, dust and drought initially followed by huge floods by melting ice in the Himalayan glaciers. The Tibetan heights on top of India are virtually under thick snow and ice. It is a giant mirror that reflects the Sun's rays back into the outer space. It keeps a lid on global warming as long as the reflective

²⁶Ibid., p. 5.

²⁷Ibid.

²⁸Ibid.

²⁹Ibid.

³⁰Ibid.

ice surface is maintained. But global warming will heat up the ice deposits, thereby accelerating the process.

The salinity of ocean is not uniform. At certain places a huge mass of water is separated by salinity difference at an interface, which is a unique ecosystem by itself. There are many such rare ecosystems in the oceans of the world. One of them is the Strait of Gibraltar. Rain and melting ice dilute the oceans causing death knell to these ecosystems. The ozone hole is already activated. It is real. Ozone is the armour that protects the world from Sun's lethal rays. Ozone-depleting chemicals damage the layer. While the lower atmosphere gets heated up due to global warming, the upper layer—the stratosphere, where ozone forms, cools down. Cooling this band of air has complex knock-on effect disrupting a chemical process that prevents ozone from breaking down. The result is loss of ozone as the world warms up. Loss of ozone will affect health security causing cancer and blindness among people.

The effects of El Niño—meaning Christ child in Spanish—are well known. It can cause drought in Asia to Australia and flooding in Ecuador and northern Peru. Originally termed to describe a warm ocean current along the tropical west coast of South America, it is now used to explain the anomalous warm ocean conditions occurring at random periods affecting weather, agriculture and fishing. It is already erratic and will become more frequent due to global warming. El Niño affects most of the parts of the world in South America and Asia Pacific.

The West Antarctic ice sheet is 1 kilometre thick. In 2002, a chunk of ice parted from the Larsen B ice shelf surprising scientists.³¹ About 3250 sq km ice was lost in 35 days. They turned up as icebergs later. Now the size of the ice sheet is 40% of the previously stabilised pack. According to estimates, the ocean will rise up to 6 metres if this ice melts.

There could be more such tipping points. The 13th pressure point not mentioned in the report could very well be the Himalayan glaciers. Already there are reports that the ice is melting at the top and the height of Mount Everest, the tallest peak in the world, has been decreasing. Against this background, it could be a disaster for India, Pakistan, China and Nepal if the Himalayan glaciers melt and worse if the sea levels also rise simultaneously. The effects of global temperature rise is visualised as follows:

- (a) Melting ice sheets
- (b) Rising sea level
- (c) Dilution of seas and subsequent changes in ocean currents and saline interfaces
- (d) Floods
- (e) Climate change
- (f) Fish stock decline
- (g) Invasion of pests and subsequent crop damage
- (h) Destruction of rain forests
- (i) Ocean nutrient level decline

³¹ Ibid., p. 6.

- (j) Accelerated increase in carbon and other greenhouse gases in the environment
- (k) Unconditional welcome sign to new ice age

Alarming? Can they be contained? Opinions vary. There is more uncertainty in the consequences of global warming than in the science of predicting it. This, probably, will be the first time the humans are concerned about global warming and its effects, though it had happened before. The choice of the species is to adapt, migrate, enjoy, die or perish to extinction. Ideally, the national boundaries will be the limits for migration. Beyond that, it will be difficult. The borders of nations will become walls of disaster. While the politicians take it cool, the scientists are a worried lot. The common people are groping in the dark while pursuing their daily chores. The scientists fear the world may not have the time to react. The results of tests so far are not encouraging. The UNIPCC has predicted the most extreme global warming—an increase of 5.8 °C. But the apprehension now is for a higher rise over the span of the coming century. Climate change, the scientists are apprehensive, could be sudden and unexpected. That will be a strike at the Achilles heel of global security itself.

There are contradictory views too. Richard Lindzen, Professor of Meteorology in the Massachusetts Institute of Technology, United States, while acknowledging that the Earth is getting warmer, and human activities have something to do with it, does not agree with the predictions that the Earth is close to doomsday by global warming. While others predict a warming of 3 or 4 °C in the next 100 years, Lindzen's calculations show less than a degree. At this figure, the current panic process including the Kyoto regime under the Kyoto Protocol³² becomes irrelevant. He questions the modelling method of the scientists in predicting the rise in temperature being inaccurate and with so many irrelevant variables included.³³ Besides emission of warming gases, warming is influenced by other factors, which are not human induced. But the fact remains that there is human-induced global warming that is still within their competence to regulate.

Imagine a scenario by looking at today's biomodel of climatic vacillations. The climate is bad and unpredictable. There are complaints everywhere—drought, floods and unusual rainfalls. But people are adapted and so are the other life forms. It is the transition point from one to another that is frightening. One day, people living in the dried up valleys of Atlantic Ocean may curse when the lush green Saharan crop yields decline.³⁴ They will speak loudly to exercise caution when it rains in the

³²Explained further in the chapter. Kyoto Protocol was in 1997, and its entry into force was on 15 February 2005. The United States renounced Kyoto protocol on non-acceptance of the requirement of mandatory reduction in carbon dioxide emissions. New discussion forums are formed, and the United States was able to appreciate the significance of such emissions and their impact on global warming.

³³Guteral, F. "The Truth About Global Warming." *Newsweek*. 23 July 2001. pp. 40–43.

³⁴In the Neocene age, the Sahara Desert was one of the best sources for freshwater. The Archipelagic waters contained monkeys and predator whales. The monkeys jumped across the mangroves, and those that slipped on a leap became the unfortunate victims for sharks, predator whales and crocodiles who lay in wait.

Amazonian desert. But environmental security does not have an eye for predicting millenniums hence. Predictions are close to generations to overcome the difficulties of the very near future—one or two generations ahead. It is global warming, the issue, that is at the fore when a question is raised, “What is the state of world environment?” The answer that comes from everyone is the bugaboo of global warming. There seems to be no escape, though, if the state of the world environment is critically analysed.

21.3.12 Climate Change

Serious discussions go on all over about climate change. To that extent everything (almost) is attributed to climate change. According to scientists climate change is here and it is happening. They agree that greenhouse gasses, both natural and those created by humans, are the main cause. Global temperatures are climbing; ice caps are melting; and droughts, wildfires, and super hurricanes are tearing their way across the landscape. The cause of climate change is attributed to global warming. If so it is an environmental security issue. It is recorded that the Earth is getting warmer. The sea levels are rising too, inundating the nearest plains. The world has decided sustainability is the answer for global warming and climate change. It means renewable energy replacing fossil energy, limiting waste and pollution and so on.

But can global warming and climate change be attributed to human foolhardiness? The causes can be traced to various other factors. Ocean, the prime mover of the planet, goes through changes, especially circulation of currents, there biotic processes that impact the planet, tectonic moves and various other natural factors of planet balancing. Human activities may play a minor role when seen from the perspectives of the law of invariance here. The natural greenhouse effect has been happening in the past too. The sea levels were rising periodically. The wobbling effects of Earth’s rotation by obliquity too are a serious matter in climate change. The Earth doesn’t rotate like a statically and dynamically balanced flywheel. A small change in the obliqueness can cause a major change in climate because of climate sensitivity.

21.3.13 Genetic Modification

Genetic modification is about engineering genes for specific objectives. Genomic research throws light into this topic. The process may attract troubles for human system as it precludes the law of natural balancing. Playing with nature, as most of the opponents of genetic engineering name the term, is dangerous. Humans need to exercise caution in gene handling to avoid chance incidents that could damage the system itself by interacting negatively with the life-sustaining environment.

21.3.14 Waste Management

Improper and unscientific waste management increases environmental stress and also risks health security. But if processed and managed well, it will not only eliminate the risk but also add value to national security governance. Waste management is intended to reduce adverse effects of waste on human health, the environment or aesthetics. Many governments around the world support constructive waste management practices though they are not uniform among countries and human systems. Waste management is a key area for governments in maintaining environmental security.

Waste management in resource usage is a global problem that heavily impacts the environment. More than waste disposal, waste minimisation could be the focus of governance. Waste minimisation through zero waste policy will require sorting, recycling, bioremediation, afforestation, sewage treatment and pollution control. The government's responsibility is providing legislative backup, enforcement, research support, identifying substitute resources and so on.

21.3.15 Biodiversity Depletion

Environment though capable of regeneration is extremely fragile because of multitudinous sustainability demands. One of them is the biodiversity that contributes to environmental sustainability. At the same time, biodiversity and environment are mutually depended. Though the environment in all probability is likely to regenerate, the time span required will not be in sync with the survival of the flora and fauna in the ecosystem. Therefore it is important to prevent biodiversity depletion for optimising environmental security through national and global governance. Loss of biodiversity reduces nature's resilience to change. Damage to environment destroys biodiversity that in turn attracts threat to its sustainability. There is a domino effect. The theme of world Environment Day in 2021 was biodiversity as its depletion has already become a burning issue.

21.4 State of the World Environment

It is a signal, when a canary drops down flapping its wings one last time inside a mine, to evacuate the mineshaft at the speed of a blink. What does it indicate when frogs, the first ever animal with backbones to walk on land and a mute witness to everything that happened so far on Earth including the birth of the bipedal, that the humans are, die *en masse*? The same—evacuate the shaft urgently. But where do they go? This time it is not the mole tunnel underground, but the planet itself in danger. The humans are far behind in identifying a new world to migrate outside the

planet. According to certain scientists, the time is running out for them. The amphibians are dying—the frogs, newts (Chinese crocodile), toads and salamanders, all are in danger of extinction.³⁵ That is a bad sign. When frogs start making an exit, the tunnel has become dark and very long for the humans. No help can come from outside. The studies carried out by around 500 scientists from 60 countries in a 3-year-long period showed that a third of the 5743 known species are threatened with being wiped out and at least 427 among them are so critical that they may disappear totally in the immediate future.³⁶ The studies also showed that 32% of amphibians are threatened with extinction along with 12% of birds and 23% of mammals (2004).³⁷ The world environment's biggest problem is that it is not showing any signs of recovery though there are some isolated signs of the vanished and vanquished coming back. The world does not know how to address this problem. It is an enigmatic decline. There is no place on Earth that has not reported unusual happenings to environment. A quarter of known land animals and plants, more than a million species, will eventually die out because of global warming that will take place over the next 50 years, the most important study of its kind has concluded.³⁸ That is the state of the world environment. Everyone, from common people to the conservationist, is in a quandary. The maximum the humans can do now is to preserve what is left behind by nature and ensure further loss is halted.

The world environment is a cornucopia of a magnificent array of life that just makes it worth for a human to live a full life totally engrossed in the mysteries of it all. The geographical terrains—land, ocean and air space—are full of life and life-supporting systems. This is a luxury that only the Earth enjoys in its solar system and in the near vicinity of it as is known so far. Beyond the solar system is not a concern, but a matter of inquisitiveness that could hold for the time being. There is life on Earth, and for all reasons one could just be in it. But somehow, the humans are seemingly incarcerated in a different destiny by their own creation. They alone can bring changes in it.

In conclusion, the state of the world environment, in spite of induced awareness and the regimes meant to protect and preserve it, is not healthy. It is deteriorating. There is general alarm and anxiety associated with the world's future prevailing over the field of development activities. It is a question of legacy that the current generation is going to leave to the next generation and that after it. "What kind of a world the future generation will inherit?" is a question in the minds of those who are concerned about the environment. It is obvious in the theme shows of the United Nation in its annual World Environment Day (WED) celebrations.

The environmental agenda is on top in the United Nations. The world continues to witness devastating storms, ice sheets melting, giant wildfires and deadly floods.

³⁵ Connor, S. "The Polluted Planet: Alarm as Global Study Finds One-Third of Amphibians Face Extinction." www.news.independent.co.uk, 16 October 2004.

³⁶ Ibid.

³⁷ Ibid.

³⁸ www.news.independent.co.uk, 16 October 2004.

One million plants and animal species face extinction according to UNEP.³⁹ This can alter life on Earth forever unless the people and their governments act (2019).

Earth is a closed planet. There is no escape route when it burns or freezes, at least not yet. Dying coral reefs, later autumns, endangered species, global warming, erratic monsoons, widening deserts, shifting ice bergs, coal bed and forest fires, hazy days, etc. have started to affect plant and animal life across the planet. In the last century, temperatures have risen around 0.6 °C. Most of it was in the last 30 years.⁴⁰ Migrating birds are changing their travel plans, cancelling bookings *en masse* much to the chagrin of their travel agents. Britain's met office predicts the temperature rise will be between 1.4 and 6° in the next century depending on government's emission policies. There are some species like painted turtle whose future is bleak even at modest rise of temperature. Climate change in the previous period, like in the Ice Age, effected differently. Today, there are 7 billion people on Earth. Migration corridors are blocked for people. They are static by force. There is no place to run. Hiding is not a solution. No way for the chromosomes to crawl across and replicate like in the days of yore when people just got up and walked across continents. There were places to go freely in those good old days.⁴¹

The vastness of the environment and its flora and fauna are reportedly dwindling. Some of them may be by natural causes of selection process. But most of the cases are the results of unregulated human intervention. Flora and fauna are indicators of environment. Conservation is remedy. There is unprecedented danger of natural process interacting with human-induced process causing a resonance that can be dangerous at certain stage. It is yet to be studied. Freshwater and wetlands are drying up or filled by construction requirement. Along with them, the freshwater and adjacent land-based flora and fauna also vanish or get displaced to alien terrains where survival becomes difficult. Wild beasts enter urban sectors in unusual invasion of the displaced. There are incidents in the city of Mumbai, India, where leopards go hunting in the city for prey from the displaced wild parks in the neighbourhood. Artificial dams and irrigation barges besides causing flash floods in the neighbourhood are also strangling water-borne animals. Animals like freshwater dolphins and dugongs get fragmented with free passage restricted. Their population dwindles. They are killed for oil or to bait fish and sometimes for protein as coping food. Today, there are only four species of freshwater dolphins seen around the world that too are in very limited numbers: the Ganges River dolphin (*susu*), the Indus River dolphin (*bhutan*), the Yangtze River dolphin (*baiji*) and the Amazon River dolphin (*boto*).⁴² Water sources besides getting depleted are also

³⁹ <https://www.unep.org/annualreport/2019/index.php>. Accessed 20 November 2020.

⁴⁰ Cropley, E. "Global warming Hits Species All Over World, Says Study." *The Times of India*, Mumbai. 30 March 2002. p. 12.

⁴¹ Climate change from sweltering heat to freezing temperatures in just 24 h was a theme of a Hollywood movie that proclaimed the coming of an Ice Age.

⁴² Panda, P.B. "Event: WWF-India Releases Book on Marine Mammals of India." Report by Kumaran Sathasivam. 12 March 2004. p. 7.

becoming contaminated at an unprecedented level. Arsenic aquifers are expanding around many of the river basins. They cause cancer to the people who live by such waters. Arsenic contamination of groundwater is a serious health problem. Regulation of tube wells and better management of water is a way out. Arsenic accumulates by oxidation, reducing condition of aquifers, microbial activity and organic inflow. Bangladesh is the most affected. According to the WHO, within a few years, one in ten deaths in south Bangladesh will be caused by cancer triggered by arsenic poisoning. Better nutritional care—food security—is a remedy.⁴³

The state of the world's forests is another area of concern. Forests are benefactors of the living. They contain a wide variety of flora and fauna. How much forest is required for a human settlement is a subject that is not yet studied. Interests in this area are divided from trees all around where there is no habitation. But forests also deplete water resources. Optimum forests for a nation depend upon purpose. It is possible to increase the natural resources by adding forests. For example, arid landscape can be changed by creation of forests. Forests also support developmental activities. But human encroachment in the name of development into the forests fractures landscapes and animal corridors.

According to Greenpeace, the international non-governmental organisation with high-profile-projected interests in the environment, 10 million hectares of ancient forests are destroyed every year.⁴⁴ Forests provide fresh air, fodder and fuel to millions and sustain freshwater provisions. The governments could follow a minimum programme to maintain natural balance with identified activities, for example:

- Preserve trees that constitute forests as well as non-forest areas—felling them are to be made on need basis.
- Plant trees and nurture them to maturity.
- Sentiments about the environment may not have a place in national security, but should be preserved to induce harmony by spiritual security—the less turbulent side of security where one can hang out comfortably.
- Prevent pollution of water that nurtures forests.
- Conserve water by optimum use and rain harvesting.
- Avoid using polythene.
- Reduce vehicle pollution.
- Use bio-fertilisers, vermicompost and other biodegradable nutrients for plants.

There are also other issues such as,

- Farmland depletion affecting agricultural production
- Groundwater depletion
- Forest fires

⁴³ Mahalanobis, S. "Poisoned Waters, Interview with Dipanakar Chakraborti." *The Times of India*, New Delhi. 21 October 2004, p. 16.

⁴⁴ "Campaigning in Defence of the Earth." Greenpeace Leaflet, 2004.

While farmland and groundwater depletion can be easily appreciated, the problems associated with forest fires cannot be easily understood, at least by those who have not experienced it. The origins of forest fires are many. Extreme dry conditions combined with high temperatures over a long period of time can be a cause. Human agency is another who starts the fire very often. *Raab* cultivation practiced by certain tribes⁴⁵ of Gujarat in India is a cause for human-induced forest fire. Haze in Malaysian skies is common when the woods burn in Indonesian forests. Pollution from abroad is a term that defines the cross boundary transgression by land, water and air. The sky gets clouded from haze as the smoke billows from Indonesian forests in the heat of summer make even the Petrona's tower, the tallest building in Kuala Lumpur, Malaysia, vanish from visibility. The air quality comes down in Malaysia causing health concerns and decline in tourist traffic besides affecting other businesses. The haze in the past also covered Singapore and Thailand. According to studies, a brown haze hangs over 10 million square kilometres of Asia.⁴⁶ But evidence lacks to connect it with floods, droughts, pollution-related deaths, etc. The study was connected with a project related to the Indian Ocean Experiment (INDOEX) that began in 1996. The study confirmed the existence of haze. The team presented their findings to the UNEP in April 2001. According to the UNEP, the haze will have profound effects on human health, crop yield and rainfall in the Asian region.⁴⁷ The haze exists in Europe and North America as well. The UNIPCC is the apex body in the United Nations on climate matters. Can the forest fires be a cause? Besides haze by forest smoke, dust clouds can also cause serious damage to the environment by changing wind patterns caused by unprecedented changes in the Earth's temperature profile. A dust cloud originated from Persian Gulf was found out to be the cause of an unusual red rain in Kerala, India, in 2003. The scientists of the Vikram Sarabhai Space Centre (VSSC) at Thiruvananthapuram, India, identified the cause after analysis.⁴⁸ The solar energy reaching the Earth is less by 15% today. Eighty percent of the 3-kilometre-thick cloud is human induced. Two million people die in India alone from atmospheric pollution annually.⁴⁹

⁴⁵“Dangis” in Gujarat, India, belongs to one such tribe who practice shifting cultivation on the move. They call it *raab* cultivation. It is peculiar to certain areas and involves in lopping the branches off the trees and then burning them in the seed beds prepared on the forest floor. Lopping the branches off the trees can be seen in many parts of forest living areas. One use is for fodder for animals. The forests are under immense stress from the tribals who do not understand the need for preservation. The Dangis burns to kill the nematodes and other insects for disease-free plants. The ash will be rich in nutrients. The farmers, however, ensure *raab* doesn't spread into a wild forest fire. But sometimes the fire goes out of control.

⁴⁷Ibid.

⁴⁸Asia Net, News Channel, 19 June 2003.

⁴⁹Mohapatra, S., and Choudhury, S. “Doubt Clouds Brown Haze Effect on India.” *The Hindustan Times*, New Delhi., 24 August 2002, p. 1.

From fire to ice is the shift to snow caps of the world. The ice caps at the poles hold the key for the world in the immediate future. Global warming can change their nature. It is already happening as per records and calculations. The dynamic and complicated body of water in the oceans can complicate the issue. The ice caps of the north and the south are freshwater oceans. While the liquid salty ocean is deep, the solid freshwater ocean is higher than the liquid sea level. In this three-dimensional ocean, the liquid and frozen waters are in a state of profound flux. If the trends persist, they could mean the solid ocean turning to a liquid and raising the level of the seas and diluting them with a serious impact on the currents. The domino effect will commence then on. The changes will lead to sharp cooling in the northern hemisphere if the Greenland ice caps melt.⁵⁰ The cooling could affect the relatively stable climatic conditions in which human societies have been evolved. The nature has to be seen in absolute reality before it is judged for its state and intentions.

According to reports, Greenland's melt zone has expanded inland.⁵¹ It can accelerate the flow of melted water into the liquid sea. The floating ice is also thinning rapidly. Such melting can speed up the seaward movement of ice. There is a need to control the discharge of icebergs to the sea. There are scientists who believe global warming is already pushing the North Atlantic toward instability. In less than 50 years, waters deep in the North Atlantic and Arctic have become significantly fresher, matched by increasing salinity in the tropical Atlantic. World-wide seas have absorbed enormous amounts of heat from the warming atmosphere. A big outflow of water from Greenland could take the system to a tipping point.⁵² The result will be deep chills and abrupt and random precipitations. There could be monumental floods from collapsing ice age glaciers. There is quite an intellectual uncertainty in defining the future since model preparations are too complicated with variables that cannot be easily ascertained. Today, Greenland is being measured and monitored as never before by satellites, by aircraft and scientists.⁵³

Far in the ocean, the coral reefs are facing the blunt of both nature with the mysterious El Niño and humans who damage them by unregulated practices. Fishing using explosives, pollution, recreation and physical damages have dwindled the coral reefs of the world that were breathtaking ecosystems by themselves. Corals bloom unhindered if they are left to themselves without touching, keeping anchorages and mooring berths for ships away, not using them as souvenirs, helping to keep the reef clean and regulating recreational diving and underwater cruises in coral reefs. But still an unexpected warm current can destroy corals in a large area. Corals are barometers of climate change. Warm ocean waters bleach them. In a worst case, 16% of world's reef building corals died in 1998. Oceans support an incredible array of life in various shapes and sizes—from microscopic plankton to the largest of the

⁵³Ibid.

great whales. Each of these species plays unique roles in the complex marine ecosystems. But many species are being (or have been) driven towards extinction due to devastating human impacts: overfishing, pollution and commercial whaling among others. The Greenpeace considers the major threats to ocean environment are overfishing, pirate fishing, whaling and intensive shrimp aquaculture.⁵⁴

Each region in the world is specific for its diversity in ecosystems. The region of Asia and South Pacific is a very diverse world in itself. Indonesia is thought to support more species than any other country, closely followed by Australia, China and others around the area. Many island nations in the area are highly susceptible to species extinction. While island geography means species can develop in isolation, it also means that if they are threatened somehow, they could be wiped out. Nearly a third of the region has no access to safe water. Central Asia is already using 85% of available water and South Asia nearly half. Per capita availability of water has dropped by 70% in Central and South Asia since 1950. In China, water use is expected to rise by half by 2025. In Australia, water use increased by 25% in the mid-1990s, compared with the mid-1980s. At the same time, the water supply has been degraded, particularly in the Murray-Darling Basin in the southeast. Some 75% of the land is expected to be altered by humans within 30 years. Indonesia is experiencing one of the highest rates of deforestation in the world, while Malaysia, Myanmar and Thailand have also seen high rates. If current trends continue, all of Indonesia's lowland forests in Sumatra will be destroyed by 2005 and in Kalimantan by 2010.

Central and Eastern Europe still have rare wildlife. Many wild lives have already become extinct in Western Europe under pressures of development. Intensive farming and encroachment on natural habitats and runoff from farms are polluting the ecosystems. Western Europe is pricing water at levels that allow for reinvestment and management of an adequate water supply. Eastern Europe and the former Soviet Union are still using more water per capita than Western Europe. In Eastern Europe, water use is estimated to nearly double by 2025. Overall, water issues have more to do with quality and ecosystems than with quantity, which appears sufficient. In Europe due to dense population and centuries of development, only 5% of the land area is designated as protected area. Finland, Germany, Norway, Poland and Sweden are regional leaders in logging practices aimed at keeping forest ecosystems healthy.

Canada and the United States are doing more to protect wetlands, critical habitats for many species, but wetlands are still being lost to agriculture and construction. In North America, the United States and Canada are the largest per capita consumers of freshwater. Supply has been abundant in the past. That might change. The High Plains aquifer, which waters a fifth of US farmland, is expected to "decline dramatically". Pollution, invasive species and cheap water add to the stress in the region. In North America, some 14% of the region's land is protected. Only northern Canada has vast unspoiled areas, but Canada and the United States are adopting practices that aim to selectively harvest forests while sustaining them for the long term.

⁵⁴ "Campaigning in Defence of the Earth." Greenpeace Leaflet, 2004.

In Africa, more than half the population has no access to safe water, fewer today than in 1990, and almost half suffer from water-related diseases. In West Africa, pollution and falling water levels threaten millions dependent on the Niger and Volta rivers. In southern Africa, water use is expected to rise by half by 2025. Another key area of threat is the invasion by non-native species that overtake an ecosystem. In Africa, half of endangered or threatened species are at risk from non-natives species. Species numbers have declined as their land range is reduced by forest clearing, civil war and wetlands draining for farming and urban development. Elephants, for example, declined from 1.3 million to 500,000 in the 1980s. The consumption of wildlife is also reducing in numbers to unsustainable levels. In Central Africa, it's estimated that more than a million tonnes of wildlife—mainly antelope, wild pigs and primates—are killed for food each year. An estimated 8% of the continent's forestland was lost during the 1990s. Some 7% of the continent is designated as protected, but most countries do not have the resources to protect wildlife from poachers, the ravages of civil war and forest clearing.

Latin America and the Caribbean hold some of the world's biologically richest land areas. Brazil, Colombia, Mexico and Peru are home to 75% of the threatened bird species in the Americas. Due to fast population growth, the region's major environmental problem of the next decade is expected to be a shortage of drinking water. In Mexico City, shortages are magnified by poor drainage, which allows sewage and rainwater to mix. In Latin America, the United Nations expects the region to be the hardest hit, with more than 80% of its land surface altered by humans within 30 years. Currently around 10% of the land is designated as protected area.

In a global scenario, a 2002 UN report warned that nearly a quarter of all known mammal species and 12% of all known bird species are threatened. The biggest factors in species decline are forest clearing, climate change, pollution, overhunting and fishing and the introduction of non-native species. Global population has altered nearly half of the Earth's landmass over the past 150 years, and the amount could rise to 70% within 30 years. That's probably the biggest factor in the decline of species. Alterations include farming, logging and urban development.

In the Middle East, coastal and marine wildlife are threatened by oil spills and other pollution, dredging and non-native species brought in accidentally by shipping traffic. Land species have declined due to over hunting, due in part to a loss of traditional management practices and the use of four-wheel-drive vehicles. This area is likely to be the worst affected worldwide, with well over 90% of the population expected to be living in areas with "severe water stress" within three decades. Increasing populations are adding to the problem, leading to regional tensions. Syria and Iraq, for example, accuse Turkey of depriving them of water by building dams along the Euphrates and Tigris rivers. Habitat destruction has increased dramatically since the 1970s due to population growth. Water use, pollution and refugee camps have shrunk the Azraq wetlands' natural reserve. In the eastern Arabian Peninsula, many of the date palm oases and freshwater springs have been lost. The United Nations estimates that if the trends continue, by 2025, 5 billion people—half of the world's estimated population—will live in areas where there will

be little or no access to drinking water. Key factors are population growth, changing weather patterns and how water is managed.⁵⁵

21.5 World Environmental Initiatives

Throughout history, national governments have passed occasional laws to protect human health from environmental contamination. For example, in about 80AD, the Senate of Rome passed legislation to protect the city's supply of clean water for drinking and bathing. In the fourteenth-century England, both the burning of coal in London and the disposal of waste into waterways were prohibited. In 1681, the Quaker leader of the English colony of Pennsylvania, William Penn (1644–1718), ordered that 1 acre of forest be preserved for every 5 acres cleared for settlement, and, in the following century, Benjamin Franklin⁵⁶ (1706–1790) led various campaigns to curtail the dumping of waste. In the nineteenth century, in the midst of the Industrial Revolution, the British government passed regulations to reduce the deleterious effects of coal burning and chemical manufacture on public health and the environment. Yet, despite this long history of environmental legislation, the field of environmental law is relatively new. Its rise to prominence began in the late twentieth century.

Prior to the twentieth century, there were few multilateral or bilateral international environmental agreements. The accords that were reached focused primarily on boundary waters, navigation and fishing rights along shared waterways and ignored pollution and other ecological issues. In the early twentieth century, conventions to protect commercially valuable species were reached, including the Convention for the Protection of Birds Useful to Agriculture (1902), signed by 12 European governments; the Convention for the Preservation and Protection of Fur Seals (1911), concluded by Japan, Russia, the United Kingdom and the United States; and the Convention for the Protection of Migratory Birds (1916), adopted by the United Kingdom (on behalf of Canada) and the United States and later extended to Mexico in 1936.

Beginning in the 1960s, environmentalism became an important political and intellectual movement in the West. In the United States, the well-known biologist and writer Rachel Carson's (1907–1964) *Silent Spring* (1962), a passionate and persuasive examination of chlorinated hydrocarbon pesticides and the environmental damage caused by their use, led to a reconsideration of a much broader range of actual and potential environmental hazards. In subsequent decades, the US government passed an extraordinary number of environmental laws—including acts addressing solid waste disposal, air and water pollution and the protection of endangered species—and created an Environmental Protection Agency to monitor

⁵⁵ www.msnbc.msn.com. Accessed 10 June 2004.

⁵⁶ American public official, writer and scientist.

compliance with the laws. These new environmental laws dramatically increased the national government's role in an area previously left primarily to state and local regulation.

In Japan, rapid post-Second World War reindustrialisation was accompanied by the indiscriminate release of industrial chemicals into the human food chain in certain areas. In the city of Minamata, for example, a large number of people suffered mercury poisoning after eating fish that had been contaminated with industrial wastes. By the early 1960s, the Japanese government had begun to consider a comprehensive pollution control policy, and in 1967, Japan enacted the world's first such overarching law, the Basic Law for Environmental Pollution Control. Not until the end of the twentieth century was Minamata declared mercury-free.

Following the United Nations Conference on the Human Environment, held in Stockholm in 1972, the United Nations established the United Nations Environment Programme (UNEP) as the world's principal international environmental organisation. Although UNEP oversees many modern-day agreements, it has little power to impose or enforce sanctions on non-complying parties. Nevertheless, a series of important conventions arose directly from the conference, including the London Convention on the Prevention of Pollution by Dumping of Wastes or Other Matter (1972) and the Convention on International Trade in Endangered Species (1973).

Until the Stockholm conference, European countries generally had been slow to enact legal standards for environmental protection—though there had been some exceptions, such as the passage of the conservationist Countryside Act in the United Kingdom in 1968. In October 1972, only a few months after the UN conference, the leaders of the European Community (EC) declared that the goal of economic expansion had to be balanced with the need to protect the environment. In the following year, the European Commission, the EC's executive branch, produced its first Environmental Action Programme. Since then the European countries have been at the forefront of environmental policymaking. In Germany, for example, public attitudes toward environmental protection changed dramatically in the early 1980s when it became known that many German forests were being destroyed by acid rain. The environmentalist German Green Party, founded in 1980, won representation in the Bundestag (national parliament) for the first time in 1983 and since then has campaigned for stricter environmental regulations. By the end of the twentieth century, the party had joined a coalition government and was responsible for developing and implementing Germany's extensive environmental policies. As a group, Germany, the Netherlands and Denmark—the so-called “green troika”—established themselves as leading innovators in environmental law.

During the 1980s, negotiations on several international environmental conventions were spurred by the “transboundary effects” of environmental pollution in individual countries. The effects of the 1986 accident at the nuclear power plant at Chernobyl in Ukraine (then part of the Soviet Union) were especially significant. European countries in the pollution's downwind path were forced to adopt measures to restrict their populations' consumption of water, milk, meat and vegetables. In Austria traces of radiation were found in cow's milk as well as in human breast milk. As a direct result of the Chernobyl accident, two international agreements—the

Convention on Early Notification of a Nuclear Accident and the Convention on Assistance in the Case of Nuclear Accident or Radiological Emergency, both adopted in 1986—were rapidly drafted to ensure notification and assistance in the event of a nuclear accident. In the following decade, a Convention on Nuclear Safety (1994) established incentives for countries to adopt basic standards for the safe operation of land-based nuclear power plants.

There are often conflicting data about the environmental impact of human activities, and scientific uncertainty often has complicated the drafting and implementation of environmental laws and regulations, particularly for international conferences attempting to develop universal standards. Consequently, such laws and regulations usually are designed to be flexible enough to accommodate changes in scientific understanding and technological capacity. The Vienna Convention for the Protection of the Ozone Layer (1985), for example, did not specify the measures that signatory states were required to adopt to protect human health and the environment from the effects of ozone depletion, nor did it mention any of the substances that were thought to damage the ozone layer. Similarly, the Framework Convention on Climate Change, or Global Warming Convention, adopted by 178 countries meeting in Rio de Janeiro at the 1992 United Nations Conference on Environment and Development (popularly known as the “Earth Summit”), did not set binding targets for reducing emission of the “greenhouse” gasses thought to cause global warming.

In 1995, the Intergovernmental Panel on Climate Change, which was established by the WMO and the UNEP to study changes in the Earth’s temperature, concluded, “The balance of evidence suggests a discernible human influence on global climate”. Although cited by environmentalists as final proof of the reality of global warming, the report was faulted by some critics for relying on insufficient data, for overstating the environmental impact of global warming and for using unrealistic models of climate change. Two years later in Kyoto, Japan, a conference of signatories to the Framework Convention on Climate Change adopted the Kyoto Protocol, which featured binding emission targets for developed countries, a system whereby developed countries could obtain credit toward their emission targets by financing energy-efficient projects in less developed countries (known as “joint implementation”), clean-development mechanisms and emissions trading. The protocol encountered stiff opposition from some countries, particularly the United States, which has failed to ratify it. The protocol came into force on 15 February 2005.

The UNEP has originated the Medium-Term Strategy 2022–2025 that provides an opportunity to care for the environment in a focused manner. But how it is going to be depends on how the people concerned in the UNEP are going to execute the planned programme. The programme will run parallel to the already existing agenda 2030 in which the environment is a leading target. According to UN secretary general António Guterres (New York, 20 September 2019), without carbon neutrality, countries will be facing more and more natural disasters, threats to public

health and a dramatic loss in biodiversity.⁵⁷ The Emissions Gap Report of UNEP asks the world to cut greenhouse gas emissions by 7.6% every year till 2030. Otherwise the world will warm more than 3 °C by the end of the century. The United Nations calls for active transformative action by all concerned: governments, regions, cities, businesses and civil society.

21.6 Levels of Environmental Law

Environmental law exists at many levels and is only partly constituted by international declarations, conventions and treaties. The bulk of environmental law is statutory—encompassed in the enactments of legislative bodies and regulatory—generated by agencies charged by governments with protection of the environment. In addition, many countries have included some right to environmental quality in their national constitutions. Since 1994, for example, environmental protection has been enshrined in the German Grundgesetz (“Basic Law”), which now states that the government must protect for *future generations the natural foundations of life*. Similarly, the Chinese constitution guarantees to each citizen a “right to life and health” and requires the state to ensure *the rational use of natural resources and protects rare animals and plants*; the South African constitution recognises a right to *an environment that is not harmful to health or well-being and to have the environment protected, for the benefit of present and future generations*; the Bulgarian constitution provides for a *right to a healthy and favourable environment, consistent with stipulated standards and regulations*; and the Chilean constitution contains a *right to live in an environment free from contamination*. Articles 48A and 51A(g) of the Indian constitution, read in conjunction with others and conclusions of the Supreme Court, state *the State and its citizens will endeavour to protect, improve and preserve the natural environment including forests, lakes, rivers and wildlife and to have compassion for living creatures*.

Much environmental law is also embodied in the decisions of international, national and local courts. Some of it is manifested in arbitrated decisions, such as the Trail Smelter arbitration (1941), which enjoined the operation of a smelter located in British Columbia, Canada, near the international border with the state of Washington, United States, and held *no State has the right to use or permit the use of its territory in such a manner as to cause injury by fumes in or to the territory of another or the properties or persons therein*.

⁵⁷ <https://www.unep.org/annualreport/2019/index.php>. 20 November 2020.

21.7 Select International Activities

The World Summit on Sustainable Development, which opened on 26 August 2002, in Johannesburg, South Africa, was attended by delegates from 192 countries, the European Union (EU) and a number of intergovernmental institutions. Participants reviewed the implementation of the Agenda 21 plan agreed to at the 1992 Rio Summit, with particular emphasis on social and economic issues. Though agreement was reached on a plan of action, environmental groups staged a walkout to protest what they saw as United States obstruction of a stronger final plan, and some opponents jeered and interrupted the US Secretary of State Colin Powell when he addressed the conference. The official four-page declaration supported the leadership role of the United Nations in promoting sustainable development and committed governments to the action plan as well as regular monitoring of progress. There was no agreement on targets for the proportion of energy that should come from renewable sources, nor was there a clear commitment to introduce rules on corporate social and environmental responsibility. The action plan set out a number of objectives. It sought to halve by 2015 the proportion of the world's population living on less than US\$1 per day, suffering from hunger or having no access to safe drinking water or improved sanitation. In the same time period, governments would aim to reduce child mortality rates by two-thirds and maternal mortality rates by three-quarters, compared with 2000. The scheme called for increased investment in cleaner technologies and greater efficiency, especially in energy supply, which would become more diverse; reiterated commitment to the Kyoto Protocol; and urged states that had not ratified it to do so. Adverse health and environmental effects of chemical use should be minimised by 2020. Children's exposure to lead was to be reduced by phasing out lead in gasoline and lead-based paint.

The blueprint of a plan to prevent illegal fishing was scheduled to be implemented by 2004 with a UN Food and Agriculture Organisation strategy for managing fishing capacity to be in place by 2005. The aim was to maintain fish stocks at maximum sustainable yields or restore depleted stocks to that level by 2015. The plan called on developed countries to try to reach the target of 0.7% of gross national product for ODA (overseas development aid), to consider measures for mitigating the volatility of short-term capital flows and to reduce unsustainable debt burdens through such measures as debt relief. Tariffs on nonagricultural products were to be reduced or eliminated. Countries were asked to formulate national strategies to implement the plan by 2005. The plan would be integrated into the policies of UN agencies.

Global Environment Outlook-3 (GEO-3) was published in May 1992 by the UNEP, 10 years after the Rio Earth Summit. The work of 1000 authors, it recorded improvements in air and water quality in North America and Europe since the 1972 UN Conference on the Human Environment and applauded the steps taken to reduce damage to the ozone layer. Overall, however, the study found that generally there had been a steady environmental deterioration, especially in less developed countries. The report divided the world into 17 regions and set out 4 possible environmental scenarios—market-first, policy-first, security-first and sustainability-first—

extending over 30 years. Market-first represented the current situation. Policy-first included stronger environmental legislation. Security-first envisaged conflicts and inequalities, with the rich withdrawing into protected enclaves. Sustainability-first assumed a global consensus on dealing with environmental issues. Even under the sustainability-first scenario, environmental improvements would take decades to emerge. The UNEP picture was repudiated by many scientists. In May, delegates attending a meeting in Washington, DC, of donor nations to the Global Environment Facility (GEF) failed to agree on a budget. The United States, which owed the GEF US\$220 million, resisted a proposal to increase funding from US\$2.2 billion to US\$3.2 billion over 4 years to cover the widening of the GEF mandate to include desertification and persistent organic pollutants. The United States felt that the GEF monitoring was inadequate and there was no assurance that the money was being spent wisely. The GEF was established in 1992 to fund the UN Conventions on Biological Diversity and Climate Change.

The world opinion about sustainable development changed with Agenda 2030 comprising 17 sustainable development goals with 169 targets (SDGs). Hopefully nations are on track and responsible to their consent towards creating a sustainable world. However, the progress depends on active participation of the authorities and agencies within the governments of a nation and between global governments. 2030 will be the year to take stock of human progress in a responsible manner for the benefit of the future generations.

21.8 Environment—Global Paradigm

Environment is a global subject. Damage in one point spreads all around through every medium transterrain. Therefore, the environment has to be governed with a global outlook. If ever there is an initiative to shed national security for global security, the element of environmental security could perhaps be the key element in the matrix of global security elements. Though such an initiative is not expected even in a far too distant future, environmental security has been an important agenda for the United Nations, the only true representative of the collective conscious of the world that comprises “We the Peoples”.

World environment initiatives by the United Nations and other agencies include celebrations, movements, education and awareness programmes, all for a purpose, besides serious conferences to regulate activities that damage environment through laws and treaties. The strategy is talk, talk, talk. . . every time louder. The world has to hear it. The communal call for cooperation is working, though slowly and differently. Government participation is a must for collective environmental security in the world. Partial success is achieved in all these efforts including those involved in specific activities on specially focused areas. The governments and non-governmental agencies are involved in it. Some of the environmental activists are also referred to as environmental terrorists under certain situations since they use violent tracks for resolving issues and cause problems for the governments. The

interlinking of concerns of various agencies causes a resonance by their amplitudes rather than objectives.

The United Nations is in the forefront of developmental activities carrying environment with them and has considerable achievements recorded through the UNEP. The UN General Assembly, by a resolution, established the World Environment Day on 5 June 1972 to mark the opening of the Stockholm Conference on Human Environment. The UNEP was created on the same day by another resolution to provide leadership and encourage partnerships in caring for the environment by enabling nations and their peoples to improve their quality of life without compromising that of the future generations. The responsibilities of the UNEP include the following⁵⁸:

- (a) Environmental monitoring, assessment and early warning
- (b) Promoting environmental activities throughout the United Nations' system
- (c) Raising public awareness on environmental issues
- (d) Facilitating information exchange on environmentally sound technologies
- (e) Providing technical, legal and institutional advice to governments

The World Environment Day is celebrated since then on 5th of June every year.⁵⁹ Various themes were promulgated each year. Table 21.1 highlights the environment day themes for the year.

Since 1974, a large array of themes was chosen, and considerable efforts have been made all over the world at various venues. The themes if observed and analysed closely will also indicate the thought process of international community on environment and the need to keep it sustainable. It also shows the pressing concerns of the period. While there are no effective mechanisms to precisely calculate the impact such worldwide activities have made in promoting environmental security in the world, particularly at the epicentre of each nation's environmental security agency—the government and its people, the United Nations can be proud of their involvement in environmental security by refusing to turn a blind eye to destructive practices all around. It is a different matter that environmental destruction continues even after so many years since the formation of the UNEP and various national agencies. The years 1998 and 2004 directed the attention exclusively to the marine environment. Kofi Annan, the UN Secretary General in his message warned the world that the marine environment was facing challenges that, if not addressed immediately and effectively, would have profound implications for sustainable development. The society could no longer view the world's seas as a convenient dumping ground for waste or as an unlimited source of plenty. The facts are clear.

Environmental movements were initiated by international communities, national governments, non-governmental organisations and communities at different stages. These include movements for the preservation of nature—against deforestation, hydroelectric projects that may submerge large areas of virgin forests, acquisitions

of agricultural land for military and industrial purposes, nuclear tests and toxic waste transfer by transportation, for the rehabilitation of people subsequent to construction of dams, illegal migration, protection of endangered species and regulating fiscal ship disposal (breaking, dismantling, scrapping and recycling). Most of these movements have contributed to significant changes in the outlook of communities though met with resistances at times making environmental security a cause for conflict. It shows absence of identity of mind in environmental security policies worldwide.

Important international movements that led to many regulatory systems are the following:

- (a) *The Stockholm Conference 1972*. The Stockholm Conference, held on 5–16 June 1972, approved 150 action plans and 20 principles to protect the delicate balance of the ecosystem in the humane environment. The Conference considered the need for a common outlook and for common principles to inspire and guide the people of the world in the preservation and enhancement of human environment. It is in this conference the idea of celebrating the World Environment Day originated and the date was chosen as the 5th of June. The United Nations resolution 2997 of 15 December 1972 deals with Institutional and Financial Arrangements for International Environmental Cooperation.
- (b) *The Barbados Declaration*. The declaration came against the background of the problems faced in environmental protection in small island states and the conference arrived at a declaration on development of small island developing states (SIDS).
- (c) *The Nairobi Conference 1982*. This conference was stocktaking on the state of the environment since the Stockholm Conference. It published a report titled “The World Environment 1972–1992”.
- (d) *The Rio Summit 1992*. It was also called the Earth Summit. It was held in Rio De Janeiro, on 3–14 June 1992, to foster “our common future”. It was a major

conference that attempted decision and expressed concern on greenhouse gas emission, forests, population, technology transfer, finance on global environmental facility and Earth's degradation. The summit ended with the adoption of the Rio Declaration and Agenda 21—a blueprint for sustainable development. The Agenda 21 is an exhaustive road map for environmental security and sustainable development at global level from which nations can derive their script for action internally and globally.

- (e) *The Malmö Ministerial Declaration, 2000*. In the first global ministerial environmental forum held at Malmö, Sweden from 29 to 31 May 2000, important and gathering environmental issues were reviewed to prepare a course of action for the twenty-first century.
- (f) *The Johannesburg Summit, 2002*. The World Summit on Sustainable Development at Johannesburg, South Africa, held on 2–4 September 2002, reaffirmed the commitment on sustainable development. The world summit recognised the most important factor of development of children in a world that was at cross-roads. It recalled the Stockholm Conference that started the awareness in the world and also examined Agenda 21 initiated in Rio de Janeiro a decade ago. All subjects—poverty, divide between the rich and the poor, global environmental issues, globalisation, etc.—were discussed, and the summit called for the commitment for sustainable development to eliminate disparities towards the welfare of people at global level. The summit covered all aspects of humankind and was not restricted to environment alone.
- (g) *Resolutions of International Maritime Organisation (IMO)*. Oceans will govern the health of the world environment in a serious manner. Routine operations, marine casualties and willful discharges can pollute the oceans to a dangerous level. The IMO is the organ under the United Nations for safeguarding the marine environment among other matters related to the oceans and shipping. The Maritime Environment Protection Committee (MEPC), one of the five committees of the IMO, has been instrumental in regulating maritime environmental aspects that include environmental regulations by protective instruments in ship recycling, ballast water management to prevent microorganisms entering alien waters, air pollution, oil pollution preparedness, response and control (OPRC), hazardous and noxious substances (HNS) pollution (OPRC-HNS Protocol), etc. The IMO is able to establish stable and viable mechanisms to prevent marine pollution by ships and by established norms including special areas (SA) and particularly sensitive sea areas (PSSA). It is an ongoing process with the MEPC under the directives of the IMO. These regulations are to be supported by national legislations for effectiveness by bringing them under national jurisdiction. Various guidelines and regulations are expected in the near future. Important among them are the following:
 - (i) Regulations to prevent transportation of harmful aquatic organisms in ballast water of ships

- (ii) Regulations for ship disposal by recycling, breaking, dismantling, and scrapping in yards over the waterfronts to safeguard against toxic chemicals used in shipbuilding
- (iii) Regulation to contain greenhouse gas (GHG) emission from ships
- (iv) Review of guidelines for sea areas to keep their sensitivity intact
- (v) Regulation of air pollution from ships
- (vi) Revised guidelines for identification and protection of particularly sensitive sea areas and special areas in addition to existing areas
- (vii) Control of harmful anti-fouling systems of ships

21.9 Agenda 2030—Possible Impact

The sustainable development agenda cover environmental security along with others, directly and indirectly. Interestingly all the 17 goals of Agenda 2030 can be attributed to healthy environment in a 2-way process. Healthy environment supports the achievement of the goals, and that in turn supports sustainable environment. It is a two-way mutually supportive process. Protection of environment was part of the original purpose of the first Earth Summit in Rio de Janeiro in 1992. Besides declaring the need for awareness, the progress was slow. Environment was again figured in the summit in South Africa in 2002, 10 years later. The present sustainable development programme for 2015–2030 is a step ahead. The governments are expected to take it seriously. The entire agenda with all the 17 goals have direct links with environmental security which the governments may exploit. Table 21.2 briefly examines them.

It can be seen from the table that the bed rock of SDGs is environmental security though SDGs overflow into almost all the elements of national security. The UNEP has dedicated programme in support of the environment in Agenda 2030. According to UNEP a healthy environment plays a key role in meeting most of the goals of the agenda. The global governments, through their people, need to pick up the pace and put greater efforts in finding better solutions to pollution, climate change and biodiversity loss in order to truly transform societies and economies.⁶⁰ According to UNEP it is engaged in the following towards better environment:

- Providing opportunities through various initiatives
- Building partnerships and strategies
- Monitoring progress through tracking indicators
- Working to ensure effective delivery of environmental dimensions of the agenda

⁶⁰“UN Environment Programme.” <https://www.unep.org/>. Accessed 24 November 2020.

Table 21.2 Environmental security factors in SDGs

Goal		Environmental concern
#1	No poverty	Protect and preserve natural environment for ecosystem goods and services that provide employment and income to people
#2	Zero hunger	Ensure environmental preservation for food resources and ecosystem services such as pollination, soil formation, nutrient cycling and water regulation that support farming
#3	Good health and well-being	Maintain clean environment
#4	Quality education	Inclusive, equitable and quality education without disruption for all
#5	Gender equality	Gender equality can be achieved by enhancing property rights and access to land and natural environmental resources to women improve their livelihood options and poverty status
#6	Clean water and sanitation	Environmental sustainability will ensure clean water, and that in turn helps to maintain healthy sanitation for all levels of people. The natural environment contributes to the management and regulation of water availability and water quality and strengthens the resilience of watersheds
#7	Affordable and clean energy	Natural environment is the primary storage place for renewable and non-renewable energy sources. Sustaining it is necessary to meet the energy demand for the future
#8	Decent work and economic growth	Preservation of natural environment will support employment and economic growth. Environment contributes resources and raw materials
#9	Industry, innovation and infrastructure	Adoption of green infrastructures can contribute to the reduction of environmental impacts and disaster risks as well as the construction of resilience in the use of natural resources
#10	Reduced inequalities	Unhealthy environment impacts the poor and vulnerable people the most. A healthy environment will reduce the inequalities
#11	Sustainable cities and communities	Healthy environment reduces pressures of urbanisation by making cities healthy which in turn can mitigate climate change impacts
#12	Sustainable consumption and production	Environmental sustainability if integrated with economic growth can yield rich dividend in economic well-being. This means the environment should be isolated, protected and preserved from economic programmes. It should lead to sustainable consumption through green programmes in production
#13	Climate action	Climate change induces erratic weather conditions. Extreme weather conditions that too at unexpected times deviating from the normals can destroy human life and property including habitats and environment
#14	Life below water	Primarily this goal is about clean oceans. The marine environment takes precedence in protecting and preserving life in it
#15	Life on land	Life on land is about wholesome environmental security. Terrestrial environment is the storehouse of a series of

(continued)

Table 21.2 (continued)

Goal		Environmental concern
		resources and habitats for all land-based systems including humans
#16	Peace, justice and strong institutions	Strong institutions are necessary to establish internationally agreed global environmental goals and establish rule of law in all terrains. There is a symbiotic relationship between human environment and natural environment. By balancing them conflict-free system with justice can be established. It is closely related to resources in the environment
#17	Partnerships for the goals	The environment is universal though they may look country specific. Partnerships among the global entities in establishing the agenda effectively can lead the human system towards achieving all the goals of sustainability within the focused target

21.10 People's Participation—The Role of the Government

People's participation is vital in governance because they are governing through the governments unless they do it directly. Direct governance is without an agent, the government. Such governance, the form of anarchy, can be totally disorganised and may lead to chaos and subsequent collaterals. But the problem in governance is that people think it is for the government to govern. It is true to some extent as the role of the government is to govern, but the people are the system entities who have to ensure the system exists for them to survive. This mindset is yet to come in people. This is natural as evolution moves at the applicable frequency and pace. But the time has come for the people to understand themselves and their participation imperative in national security governance through their respective types of governments. In the reverse, it is time for governments to ensure people's participation. Governments should absorb people's participation in their role of governance. This alteration in the process, ensuring people's participation in governance, can offer rich dividends. There are no governments who have mastered this art in the world today.

Though people's participation applies to all the elements of national security in every terrain, it is not urgently required in governing environmental security as it matters to each and every individual. The evidence lies in the environment-friendly traditions and customs followed by many human systems *ab initio* on dealing with nature and the natural environment which is also incorporated in some of the constitutions. The author has highlighted this matter in his book *Marine Environmental Security: Management and People's Participation*.⁶¹ People's active participation in governance is becoming an important point of discussion, highlighting human awareness on well-being as an important function of people's cooperative effort. Here the people are not those employed in government but the citizens who

⁶¹Paleri, P. (2009). *Marine environment: management and people's participation*. Knowledge World.

are not in direct governance. People's participation means the involvement of all in national governance towards the identified objective. This mindset is not easy to overcome, and there can be many restrictions and thought processes against supporting a government whom people have accepted under non-acceptance for various reasons. But in matters that have direct impact on people such as environmental degradation, it should not be difficult to get people's participation. People's participation means that people are involved in governance that affects their lives. Environmental security is an element where people's participation can be introduced at this stage. It is part of the role of the government not any other non-governmental agency by direct intervention similar to stakeholder engagement. People are the prime stakeholders of governance. The term people's participation is used in this study to contrast with other terms such as public participation, citizen's participation, etc. highlighting GBNS. Here people take care of governance through their respective governments for maximising their own collective well-being as the ultimate goal of national security. Though it is not easy to achieve it, a beginning can be made with the government emphasising the concept directly as stakeholder intervention and engagement applying and regulating the salience in the system.

21.11 So What Is Environmental Security?

Environmental security, in this study, is the 13th identified element of national security in the chronological hierarchy of 16 elements. Environmental security, "envirosec" in short with the symbol " e_{s4} ", is about the protection and preservation of natural environment and prevention and control (P^3C) of environmental pollution. It means governing the natural environment against all the threats attracted by it in a sustainable manner for the benefit of all life forms that in turn impact on human well-being.

21.11.1 Definition—Environmental Security

Against this background, environmental security means *the capability of a nation to sustainably maintain its part of the natural environment by protecting and preserving it and preventing and controlling pollution, responsibly and constructively contributing to global environmental sustainability, perfectly aligned with the other elements of national security and integrated with all the terrains of national governance.*

21.12 Summation

Environmental security is about the living systems and their survival on the planet. It is the responsibility of the people and their governments to make life sustainable for the future. Environmental security examines the threats posed by environmental events and trends to individuals, communities or nations. It may focus on the impact of human conflict and international relations on the environment or on how environmental problems cross national boundaries. Natural environment holds life firmly in a cup. Though many life forms have become extinct, the environment of the humans is still vast with astonishing statistics on life and its destruction. The solutions have to come from the people-oriented grass root and community actions.

Governments will be able to overcome the issues with nature by legislation and enforcement involving people by direct participation in environmental activities, raising environmental awareness among public and various other stakeholder interventional programmes. The problem can be serious when governments themselves decide to alter the balancing gradient of nature. Altering nature will make it turn vicious without remorse as in the case of the Aral Sea (Box 21.2).

Box 21.2: Governance by Destruction: The Aral Sea

Governance by destruction is following the policies that otherwise may look constructive but ultimately leads to destruction. It could happen when the governments act in haste without serious thinking and studies. The erstwhile Soviet Union in a hurry to develop the farm sector diverted two critical rivers, the Amu Darya and the Syr Darya flowing into it by linking them with the farm lands in the 1950s. The intervention resulted in the drying up of the biologically diverse Aral Sea and its interfacial marine environment (IFME).⁶² The Aral Sea that once had 1100 islands dotting it is a ghostly arid desert with a small briny water pool in it today. With determined efforts the Aral Sea can still be restored.

Greenhouse gas emissions, land degradation, overexploitation of natural resources, ocean pollution and now the debris circling the planet in the contiguous space and many other factors of habitat neglect by those who should be protecting them, the humans, can turn disastrous in the future, especially when the point of no return is reached. The good news is that the people and governments are aware. The annual conferences at the United Nations on climate and environment and specific discussions on various other platforms around the world indicate the human will to fight against the odds for sustainability. Environmental security, thereby, is a challenge for every government and citizen.

⁶²Paleri, P. (2009). *Marine environment: management and people's participation*. Knowledge World. p.37–79.

Chapter 22

Cyber Security (Cybersec) (c_s)

In national security, 'cyber security' is not the much talked about 'cyber security'; it's more

22.1 Introduction

Cyber security as an element of national security is an “impossible” element for assured cyber maxima. The term “cyber maxima”,¹ used here, means the edge of the dimension of the element for national security governance, explained as a terrain in this study, where the element survives. The terrain, cyberspace, is only perceivable within the human intellect. It is not reachable in its entirety, at least at the moment and immediate future. Cyberspace, sans most of its access support systems, doesn’t have an edge, nor is multidimensional where edges are not easily definable. Expanding the element of cyber security to the limit remains a maxima concept where the limit is neither existing nor perceivable with clarity. Cyber security influences all terrains but remains within its own. Cyber security is the only identified national security element in the terrain dimension of cyberspace at the moment. This situation may change in the not-so-near future with additional elements getting identified in the cyberspace by expansion and differentiation. This also shows that the topic of cyber and allied technology is not yet advanced as many depict it in a restless aggrandisement. It has just begun. There is much left in the future for advancement. Many of them may pale present-day cyber technology that the humans think is ultimate in awe. It also has a rhythm that this study doesn’t think is speeded up; instead it is naturally constant. This study is a bit surprised about the unusual slowdown in the development of cyberspace and information technology. Perhaps the critical sluice gate in human advancement in cyber technology is yet to open. Or rather the direction or course it is taking may require change. That is not part of this study.

Cyber security is widely used as a term to mention security of computers, softwares, networks, externals, neural systems and many associated others in its common semantic appreciation. The term cyber originated from the 1940-term cybernetics,² a technical subject that dealt with control systems that were interactive between humans and machines. Cybernetics too is an ancient term originated from the Greek, *kubernetes*, referring to a helmsman or pilot at sea. It is defined as the “scientific study of control and communication in the animal and the machine”.³ Big fallout of the study of cybernetics was in psychology and self-development which also developed seriously during Cold War in a hurry for the then powers in their efforts to outwit each other. Cybernetics was a fad in those days among technologists, scientists and, as mentioned, even psychologists.⁴ Today cyberspace and cyber

¹The term is in plural, whereas the objective of national security governance is maximisation of cyber security which is cyber security maximum. There the term is used in singular.

²Actually it is understood that the term cybernetics was first used in the context of the study of self-governance by Plato in Republic and in Alcibiades to signify the governance of people.

³Wiener, N. (1948). *Cybernetics: or control and communication in the animal and the machine*. The MIT Press.

⁴The term psycho cybernetics was used in self-development coaching and other personality development programmes, especially during the Cold War periods by both the powers on the political polarity.

security stand different from mere human-machine (humach) interaction or personality development. It is a changed subject with a dimension of its own.

Cyberspace, as an identified terrain of national security, was waiting to happen. It was there on the highway of human intellectual evolution as a hitchhiker leaning on a milestone. The transterrain pathways of human intellect from fire to cyber and beyond through farming, domestication, prime movers, communication, aerospace, interstellar and others at different stages are bound to happen as an evolutionary continuum whether along straight lines or surges.⁵ Two more terrain dimensions have already been identified in this study after cyber—genome and microbiome. They too will be heavily influenced by it. Human intellect, in its evolutionary movement forward, is not expected to stop. It also indicates that governing the humans is not going to remain an easy job as time passes and more and more terrain dimensions evolve and elements get identified.⁶ The future of the cyber world and its development are also hidden in this statement. Cyberspace is a non-physical terrain where humans cannot move physically. It permits transfer of information using hardware, software and applications (including cloud-based applications⁷), networks and, the mother of all nets, the Internet (Box 22.1).

Box 22.1: Applications, Web and Cloud in Cyberspace

Cyberspace is a non-physical terrain where information is directed and navigated. The transportation is supported by applications, web or cloud. Application is a program designed to help people perform a desired activity by manipulating (negotiating) text, numbers, audio, graphics and a combination of them. Web has many meanings in computer science. But for the basics, it is a network that connects systems and also refers to the World Wide Web (www). Web comprises pages (electronic documents) formatted in HTML (hypertext markup language) and connected by links called “hypertext” or hyperlinks and accessed by HTTP (hypertext transfer protocol). Cloud is meant by cloud computing, which is an abstract term used to describe services provided over a network by a collection of remote servers. They provide distributed storage and processing power that can be accessed by any Internet-connected device running a web browser.

Appearance of a new and different terrain in the realms of national security is only the beginning and, perhaps, with a message that more will follow in the course of time. From here on, all those new additions in terrain configuration will be different. Kautilya, Sun Tzu, Machiavelli, Clausewitz or any of the early strategists would have never imagined such terrains could exist one day. But the strategic principles

⁵Forward and backward movement in a billowing fashion at any time.

⁶This is a hypothetical statement. Perhaps multiple terrains can make governance easier if put to use diligently by governments by integration.

⁷Comprising hardware and software with applications as if hiring a womb.

propounded by the wise people of the past will continue as long as humans remain as modified primates with primitive instincts—a primate gone mod in the fashion street of evolution. Internally, the primateness is very strong in humans. The theme of thinking has changed with the invention of computers and, more, with their connectivity. In human endeavours and advancement blessed with the most fascinating intellect that any living organisms ever had, these are not surprising events. They were bound to happen through human activities. Along with facilities, such advancements also bring adversities.

Computers advanced from the earliest Mesopotamian⁸ abacus⁹ (2400 BC) to the millennium supers reaching beyond 1.5 exaFLOPS meaning 10^{18} floating point operations per second (Box 22.2), aiming at yottaflop (10^{24})¹⁰ in a few years' time. FLOPS is a measure of computer operations. It is useful in scientific computations that require floating point calculations than measuring instructions per second.

Box 22.2: Floating Point Arithmetic

Floating point arithmetic is used in computing. It is arithmetic using formulaic representation of real numbers¹¹ as an approximation to support a trade-off between range and precision. A floating point system can be used to represent, with a fixed number of digits, numbers of different orders of magnitude (e.g. micro- to macro-distances).

Coming back from cyber ballooning (author's term for sudden deviation enroute during a communication transaction), it is important to understand that cyberspace is the virtual or the unseen and unfelt domain of the “chips” on a plate sans the fried fish, also called microprocessors that opens into the world of semiconductors usually made of silicon (Si) on which the integrated circuit is embedded. The integrated circuit contains the memory and processing units of the modern computers unlike the analogue computing systems of the past starting with the good old abacus. It is interesting how silicon plays the part of making the space. So far it is only silicon

⁸Unproved information.

⁹“Abundant Beads Addition and Calculation Utility System.” But, in Latin, the word abacus means a reckoning table covered with dust.

¹⁰The performance of supercomputers is presently measured in floating point operations per second (FLOPS) instead of million instructions per second (MIPS). Since 2017, there are supercomputers which can perform over a hundred quadrillion FLOPS (100 petaFLOPS or PFLOPS). The measure of FLOPS in descending order is yottaflops (10^{24}), zetaflops (10^{21}), exaflops (10^{18}), petaflops (10^{15}), teraflops (10^{12}), gigaflops (10^9), megaflops (10^6) or kiloflops (10^3).

¹¹A real number is a value of a continuous quantity that can represent a distance along a line. A real number is any positive or negative number. This includes all integers and all rational and irrational numbers... For example, a program may limit all real numbers to a fixed number of decimal places. Zero (0) is a real number and are all numbers that can be placed on the left or right of it on the number line

chips that are used in computers. They are made of silica (SiO_2), the main constituent of sand.¹² This is in spite of not being the best among the optimally acquiescent electronic materials for building the “space”. But it is cheap and universally abundant. It makes the cyberspace affordable to the world. Silicon domination in the cyber world will continue until a better and cheaper material is found. Perhaps this research to find a better chip material may transform the cyberspace and revolutionise computing completely. The technology is of semiconductors—neither a conductor nor an insulator of electrons. The advantage is that one can switch a semiconductor between an “on and off” state at room temperature, the normal temperature. The conductivity can also be regulated with dopants (impurity atoms). Semiconductors are just the right material as identified today. Silicon may not be the best, but it is respectably polite and amenable to the job. No wonder the world has fallen for Si.

Of course, there are other materials with better electronic properties. Two of them are germanium (Ge) and gallium (Ga). Both of them are widely used in electronic circuits, semiconductors and so on. They are not naturally found. They need to be extracted from their source materials. There are other materials too. A computer chip needs to be built with semiconductor material (in between a conductor and insulator) for which silicon has been perfected in process and design. Entry of silicon as the preferred semiconductor is since 1950 as it has many advantages over the other materials. But it may not continue once it is stretched to the limit of its semiconductor capabilities demanded by chip architecture.

The world of cyberspace is vast. Cyber security is the only element in the terrain at the moment and most probably for some more time. It is interactive and integrable with all the other terrains and elements. The subject is relatively young. There is a distinct age and personality difference between cyber professionals and the rest of the majority professionals in the world. The element, the terrain and the practitioners possess a kind of “cyber personality” that is distinct and differentiable. It may not be wrong to say that the cyber professionals display energy and competitive verve with a rage of insatiation. There are gifted whiz kids in cyberspace. A generous examination of the cyber world will show that the people who contributed vastly to it did it in their intellectually firebrand young age. They were unstoppable. It was not mere competition. According to the author, the cyber professionals were competing with themselves. This is an interesting find in the study of human investment management postulated by the author, especially applicable and identifiable in the cyber field.¹³ Cyber security is a young subject that is growing up in hurry and perhaps the field for the competitive young who could also be old by age.

¹²The composition of sand will depend on the rock sources and conditions. The most common constituent of sand is silica (silicon dioxide or SiO_2).

¹³Paleri, P. (2018). *Human investment management: raise the level by capitalising human*. Springer Nature Singapore Pte Ltd.

22.2 Cyber Security—Setting

Cyber security is a comparatively recent and fast-evolving element of national security. It is identified subsequent to the entry of the cyber terrain in the continuum of national security. It has virtually and dominantly transformed the world for the better. Such trends are the proof that the world of humans is advancing, not retreating. The most important aspect of the terrain concept in national security is that once entered in the national security concept, they will not go, instead establish firmly by an extraordinary interlocking between them. The elements may transform. Cyber security as an element is new and recent but not nascent; it is a well-established onscene in national governance.

Cyber terrain and the element of cyber security are everywhere and in everything in the world today. Cyber security is thus important not only because of the actions of individual participants but also being fundamental to the functioning of national and international systems covering every aspect of national security governance. It is also, therefore, a critical threat attractor. Cyber addicts find thrill and adventure in cyberspace. There are good and bad cyber chums. The cyberspace has given a sense of self-control and power to people. That is one of the reasons why anything is possible in this terrain. The outcome, whether good or bad, depends upon the psyche of the players addicted to it. When negativism plays in their mind, the result is one of the dreaded affairs of cyber security, the problem of protecting information and the terrain—hacking, unauthorised entry. Hackers plunder more ruthlessly than the butchers of the other terrains, especially the thundering barbarians of terra firma or the stealthy pirates of the burning seas. It also means the boundary breach issues in cyberspace in national security parlance. This calls for extra vigilance in cyberspace because it may not end up with mere hacking to loot. More tricksters will come up with advanced tricks than the previous ones. In between the intellectual lunacy and balanced behaviour, the demand for cyberspace will increase, and the terrain will expand. It will also carry associated problems that a terrain may bring in with organisational actors playing the main role. The terrain is only a canvass. The government, being accountable to the people, has a role to keep the cyberspace safe for all who are in it, the cyber people, the data and the supporting systems.

The cyber world is not just computers, data, networks, connectivity, clouds, applications and the input-process-output (IPO) systems. They make it only a part of the information systems. Connectivity creates one big computer out of all those smaller ones connected, making a data conglomeration. Connectivity is upgraded in usage by the Internet, a wonder that breathed life into the whole system of cyberspace. The Internet was born on 19 September 1969,¹⁴ when Berners-Lee conceived the idea of the World Wide Web (www) around 1989. He did not patent it for his own reasons. Perhaps the security concern today would not have been so big if he had done that. It would have brought certain restrictions *ab initio* on cyber freedom leading to higher security. On the other hand, it would have also blocked the freedom

¹⁴ Nag, n. "The New Effect." *Hindustan Times*, New Delhi.. 19 September 2004. p. 17.

of operation that has brought such a revolution in informational management after the invention of information material—from scrolls to telephones to media. The World Wide Web became free that so many could use it.¹⁵ That is just what the cyberspace did, besides opening up a domain of infinite hope for humans in their survival quest. But what if it had the blessings of the military establishment? Perhaps that will answer the associated openness.¹⁶

The Internet had many title holders in various fields—for network interconnection to communicate, email, hypertext, etc., among scores of other contributions. Bernes-Lee, mentioned to be the original conceiver of the World Wide Web, called it a “mesh” before changing to “web”. The term “web” sounds more appropriate to the problems it can also pose.¹⁷ A web can disorient. That is the real problem with cyber security. That is where the threat hides in various forms and shapes. The forms and shape will change as and when the web expands and carries more information inertia. The cyber maze comprised many passageways and barriers initially: the browsers, www-the address, interoperable hypertext, e-mail, markup language, uniform resource locators (URL), hackers, spams, viruses, bugs, pop-ups, malwares, illegal franchises and everything else. It is a mesh, not a mess with all of them and more. Today there is a flurry of them in different cadences. Their genre will only increase. The World Wide Web stands alone being licence-free. If there were insistence of imbursements, there would have been more webs in the world today. The question is whether it is good or bad from the point of view of cyber security. Did it cut the competition? It is against the projected finding of this book to ask questions on matters of opportunity, especially the “what if” questions. It is not appropriate in strategic thinking where reality matters and not opportune realities.¹⁸ There is no opportunity question in decision-making once a decision is taken.

Cyber is creativity oriented. Stifling creativity, therefore, has no room in such a terrain. It is a terrain where creativity will run amok. And there is enough room for adverse creativity. The Internet business did not reach the expected peaks in the early days. It crashed immediately after take-off. Very few made profits. For most, it was loss. Advertently the terrain is pandered by deceit, fraud, porn, treachery and swindling—the paradigm of using advanced technology and intellect for lowbrow interests of mass appeal under criminal mindset. It became a graphic haven for abominably written prose, horrific images and the sweaty sensibility of a romp

¹⁵Shannon, V. ‘Father of ‘www’ Gets \$1.2 m Prize. *Hindustan Times*, New Delhi. 19 September 2004, p. 17. The Finnish Technology Award Foundation awarded Bernes-Lee US\$1.2 million in prize for outstanding technological achievement that raised the quality of life. The Finnish government and private contractors supported the foundation. He was the first recipient of the prize. There were 78 nominations decided by 8 judges.

¹⁶The evolution of the Internet commenced from the needs of the military. Subsequently it expanded to the purpose of scientific communication. The invention also came about in part by the increasing need for computers in the 1960s. All these make the Internet an advanced evolution in the scientific domain of information technology.

¹⁷*Ibid.*

¹⁸The future of cyber security has a lot to do with geostrategic security measures.

through the febrile fantasies of perverts. Hate is sown, bred, harvested and spread in cyberspace. Rumours and lies can ferment in cyberspace. One of the reasons is that the Internet businesses that thrive most readily are the kinds that do well in every medium including those who sell titillation. Every industry has its charlatans and shenanigans, and the cyberspace too has its share.¹⁹ It has become a perfect terrain for all-out conflict in national security.

While the Internet has transformed the workspace, there are other points of concern too. According to reports, one in four employees is hooked on the Web (2002) though majority of employers don't agree.²⁰ Employees spend on the average more than a workday each week surfing non-work-related sites while at their desks. Pornography, news, e-commerce, entertainment and gambling sites are among the popular online destinations. People access the cyber world for personal and official reasons.²¹ This is indicative to wide usage of cyber terrain in every human endeavour. The trend is expected to continue more vigorously. Cyber security, the element, is highly futuristic when it conjoins the evolving artificial intelligence (AI) whose trend is not easy to estimate as it is situational and need based. With all these goings-on, the element, "cyber security" cannot be discounted under any circumstance in national security governance. It has to be seen in its clear perspective for assimilating with other elements of national security. Cyber security as an element of national security is special, because it is the first and the only element presently associated with the cyber terrain.

And it is important to remind oneself that unlike in the physical terrains, the space to manoeuvre in cyber and other non-physical terrains is external to the "vehicle" designed for access into it. Those in governance should know.

22.3 Vulnerability and Threat Attraction

Threat to any element of national security is in perpetuity. It is applicable to cyber systems also. It needs to be access controlled against unauthorised entry by threat actors. The threat actor exploits the vulnerability of the system. The access is not simply physical. That is the difference. The vulnerability of a cyber system including the network refers to the defect in it or its latency to attract threat that can leave it open to violation and disorder. The vulnerability refers to any type of limitations present in the system that will make it weak, porous and exploitable. Vulnerability makes the system submissive, wearing the ability to hold and defend. Vulnerability

can impact a small office/home office (SOHO) to national and global cyber informational grids and networks.

In some studies vulnerability is separated from threat. Vulnerability is considered as an inherent weakness or flaw, whereas threat is taken as an external effect. But in this study where threat is combined in the threat matrix format jointly with the target (threat and target exist only in a mutual format) vulnerability and threat of any kind are interrelated to the extant vulnerability itself which becomes a threat. This is the same with what computer vulnerability experts also mention, though differently. According to them vulnerability applies to the computer and network asset (computer, database, application systems and network), whereas cyber threat is external to them, homing on to the system intentionally from an outside element. Cyber threat actors that include individuals, groups and professional or official agencies will leverage the flaws in their attacks, leading some to use the terms vulnerability and threat interchangeably.

Cyber security, the term used for cyber information security, needs to be inherent to the system in the governance of cyber security, the element of national security governance in the overall national security. It calls for a systematic approach in analysing the effectiveness of an overall security system for a particular facility or the national security system itself. Any computer system is accessible to unauthorised people to subvert security for malicious purposes if determined using tools programmed for such purpose. They progress parallel to the system tools. Threat characteristics change every moment. Therefore, vulnerability analysis and preventive measures have to be integrated within the system itself as an ongoing process, thereby cataloguing for incidence response.

Important in this effort is designing a cyber threat framework (CTF) to facilitate organising and examining the overall adversarial activity that will jeopardise security of information and system. With a multipronged threat framework in place, the users of the system will have an all-encompassing security system that will not be just operating system based and dependent. Here the effort is not to reduce the threat attractiveness but to defend information however advanced and attractive the cyber activities may be. The advancement of the cyber activities for national security is allowed to continue without hindering growth in the name of security. That means the threat framework should run parallel to cyber advancement as a part of the system.

Assessing the security posture of a system includes charactering the system and its operation. The system in vulnerability analysis means the facility or network as a whole along with integrated cyber system within it. Computer networks have grown over the years. There are total connectivity environments today with the Internet and a large number of captive networks and information systems in place in any domain. This is going to stay and further advance at breathtaking pace by competition wheeled out by necessity. It will be cyber advancement at the speed of thought.²²

²²To borrow a term from the title of a best seller, *Business @ the Speed of Thought* by Bill Gates. (1999). Grand Central Publishing.

Though an unusual prospect and exaggeration (thought is faster than even the fastest of what we perceive today—did someone say light?²³), it only accounts for the growth of information technology.

Notwithstanding, the management of computers and cyber-based information systems has become a major task particularly with regard to computer and network security. The fast changes in technology also place further constraints on systems, and classified services in particular, due to the sensitive nature of work. Cyber security demands state-of-the-art infrastructure within each organisation with gateways between interactive organisational networks that need to be managed with properly defined architecture and interfaces. The security policy and procedures should be capable of deriving maximum advantage from public infrastructure with suitable security overlay providing highly reliable and secure systems of communication critical for today's activities including military and non-military security operations.

The number of computer users is increasing. The Covid-19 lockdowns have everyone (well, almost) cyber savvy. Many depended on computers for online transactions. These transactions cover business, banking, mail, trading stock, managing personal accounts, sustaining relations, etc. This is an ideal situation for fraudsters, data thieves and pranksters to enter into the private world of the computer user and cause havoc in the personal cyber world. Scammers are at the edge to take advantage of the rush for cyber demand for services. Online fraud is just one of the problems of cyber security that is growing.

The prime targets are all sensitive financial, political, strategic, military, corporate, etc. organisations. In addition individuals are also targeted. The term used for breaking into cyberspace is called phishing.²⁴ The phishing scamsters send e-mails that appear to be genuine as in most of the cases of fraud and are connected to a URL that appears to be genuine. The unsuspecting customer gives away personal data including passwords that could be manipulated to online fraud thereafter. The websites are spoofed and not genuine. More than 3 billion fake e-mails are in circulation in the world every day (2019).²⁵ The fake e-mails are meant to phish or spoof individuals and organisations.

Hacking into defence- and security-related matters normally would have the motive of intelligence gathering and deliberate attacks to destroy systems.

The problem is also that of the enterprises. The companies should be concerned about it. Breaching customer accounts will erode confidence, and online transactions will be withdrawn. That, in turn, will affect economic security. Online usage

²³Thought cannot be compared with light as they operate in different domains and possess entirely different characteristics. The statement is to highlight the speed of cyber advancement with a bit of exaggeration.

²⁴Unmesh, Deshmukh. "Arm against Online Fraud." *The Economic Times*, New Delhi. 30 September 2004. p. 9.

²⁵"More Than Three Billion Fake Emails are Sent Worldwide Every Day." <https://www.securitymagazine.com/articles/90345-more-than-three-billion-fake-emails-are-sent-worldwide-every-day>. Accessed 20 March 2020.

awareness as well as enterprise centred protection system under a national policy or international policy is the solution. The threat is real. This one is called the phishers. They are direct, external and covert. Controlling cyberspace is not in isolation of a particular system, but through technology management.

22.4 Vulnerability Analysis

Vulnerability analysis examines in depth the security posture of the organisation's system profile. It will include characterising the system, defining the threat, identifying security targets, determining security system objectives, identifying existing physical protection system elements and analysing the effectiveness of the security system including identifying any deficiencies. The vulnerability of an electronic system is embedded in the property of the system, its attendant software and hardware or its administrative procedures. The system is vulnerable when a user can access it without authorisation. Permission to unauthorised entry is invitation to disaster. An unauthorised entrant can access and modify the system and steal or alter data at will. The unauthorised entrant thus exploits the vulnerability of the system. The risk involved is the possibility of loss applied to information system of the organisation. It is generally defined as "the possibility of loss". As it applies to information technology, risk is "the possibility for loss of availability, integrity or confidentiality due to a specific threat".

In risk assessment, the likelihood of occurrence of exploiting vulnerability is measured in terms of loss to assets: buildings, computer hardware, laptops, e-mail, software, databases, etc. Assets are all those that have value to an organisation. The effectiveness of any risk assessment process relies on the accuracy and completeness of the inputs. Data is vital. Unfortunately, almost all risk assessment methods used today do not provide a method to accurately assess the threats facing a large networked environment.

In cyber security, identification and evaluation of threats is a complicated, multidimensional process. This process involves analysis of multiple technologies and how they interoperate. It involves the analysis of methods, access, skill levels and costs required to exploit a given weakness. Threats to information assets are not limited to technological weakness. Physical controls, business and operational processes, telecommunications, employee awareness, etc. play vital roles. Not all threats are malicious. Accidents, errors of omission and natural disasters are equally likely threats that require consideration in cyber security.

Risk assessments only provide a snapshot of vulnerabilities in an ever-changing dynamic system. In large networks, there are continuous changes in the number and type of systems, connections and software. Information and physical assets, potential safeguards and business requirements are always evolving. Therefore, risk assessments must be part of an ongoing process reevaluating old vulnerabilities and identifying new ones. Only after actual threats and vulnerabilities are understood can policy and risk management decisions be implemented. Because of the

complexity and effort involved in analysing these multidimensional factors, a separate “threat assessment” is required. Traditionally, threat assessments attempt to determine what threats exist, their likelihood and the consequences or potential loss.

22.4.1 Types of Vulnerabilities

Vulnerabilities exist throughout information system processes and in software, hardware and information management. There are many types of vulnerabilities:

- Physical: sabotage, theft, vandalism, etc.
- Natural disasters and environmental threats: fire, flood, power loss, etc.
- Hardware and software: misuse, compromise of integrity, fraud, failure, etc.
- Media (storage devices): theft, damage, etc.
- Emanation: radiation interception
- Communication: interception of message, rerouting, etc.
- Human: system damage due to greed, blackmail, etc. of those who administer
- Unauthorised entry: hacking, phishing, etc.

Another way of expressing the security vulnerabilities are as based on the location—where it exists. Some of the broad categories vulnerabilities are mentioned below.

- Network: issues with a network’s hardware or software
- Operating System (OS): vulnerabilities within a particular operating system such as default superuser accounts in some OS installs and hidden backdoor programs
- Human element: human errors that expose data, create exploitable access points, cause disruption, traffic information, plant malware or act in any undesired manner in cyberspace either deliberate or by incompetence
- Process: ineffective process controls, absence of process controls and many others that compromise process security

The common vulnerabilities that can affect a cyber system include the following:

- Bugs
- Weak passwords
- Software that is already infected with virus
- Missing data encryption
- OS command injection
- SQL injection
- Buffer overflow
- Missing authorization
- Use of broken algorithms
- URL redirection to untrusted sites
- Path traversal

- Missing authentication for critical function
- Unrestricted upload of dangerous file types
- Dependence on untrusted inputs in a security decision
- Cross-site scripting and forgery
- Download of codes without integrity checks

22.4.2 *Vulnerability Evaluation*

Vulnerability evaluation is what to look for in the computer system. The answer is “everything”. However some of the specific aspects are examined below.

- **Sabotage.** Sabotage is the generic name given to the class of deliberate and directed attacks, which damage or destroy assets. A sabotage attack can be a physical attack on the facilities like communication lines, computer equipment or an electronic attack on software or data. A virus written to attack a particular site or software product would constitute an electronic sabotage attack. Logic bombs are a particularly significant sabotage threat whereby disgruntled computer staff put hostile program code into a computer system to be triggered at some later and generally predetermined time.
- **Asset theft.** Theft involves taking items with an intention to permanently deprive their owner of possession or for petty considerations. Portable microcomputers are particularly at risk since they can be flipped easily. Internal components of a computer system, such as hard disks and add-on boards, are also easy to remove, and their absence will be detected only when the system is used next.
- **Identity theft.** Identity theft is stealing somebody’s vital personal information and using it for access and benefits under the stolen identity. Cyberspace provides ideal playground for such dark activities on the web.
- **Vandalism.** Vandalism is carried out through virus, worms and other malignant programmes. Such programmes may be relatively benign with the attack phase doing nothing more than playing a tune, or they may be quite malevolent. Viruses are not directed and will attack any host they happen to infect. They are particularly insidious. While dormant viruses can spread covertly throughout the computer systems before beginning their attack cycle. With large numbers of microcomputers being used in departments for day-to-day activities and as departments move more into open architecture technology, the risks of infection increase substantially.
- **Fraud.** Computer fraud is a criminal activity prevalent in financial systems. It is not an attack on the computer system directly. It is an activity that misuses a computer system for fraudulent advantage. There are four commonly known attacks: deception, salami attacks, ghost employees and phony claims. Deception occurs when an attacker identifies himself or herself as an authorised recipient and obtains money that rightfully should be provided to someone else. Salami attacks are those that take a small amount of money from many accounts,

typically during such operations as interest calculations. Ghost employees are fictional employees created for the purpose of fraudulently obtaining payroll funds. Phony claims are fraudulent claims authorised by an authorising officer.

- **Misuse.** Misuse of software and data is the unauthorised access to the use or copying of software or data. This can be done remotely if systems allow outside electronic access through dial-in or network connections. The simplest form of misuse is copying data files, which in many cases will be difficult, if not impossible, to detect. Software piracy is a problem of misuse rather than theft as the software is copied rather than stolen.
- **Interception.** Interception of automated information occurs primarily in four ways: overview, communications interception, interception of electromagnetic radiation (EMR) and data interception within a computer system. These are described below:
 - **Overview.** Overview involves gaining visual access to information, typically from some distance away. It may sound simple, but hard copy documents and computer screens located near windows are vulnerable to overview.
 - **Communications.** Communication lines connecting independent computer systems are vulnerable to interception by line tapping, by close proximity induction or, in the case of fibre optic, by a form of refraction known as cohesive detection. Radio frequency and cellular communications are particularly vulnerable to interception. Of particular concern in data communications is the common practice of sending user identification codes (user ID) and passwords from remote terminals to their host computers without using any form of data encryption. If this information is intercepted, then access control to the host will be totally compromised. This vulnerability is particularly significant, if public networks are used as the communications path.
 - **Electromagnetic radiation.** Commercial computer equipment generally conforms to national standards for limiting radio frequency interference, but the equipment still emits significant electromagnetic radiation (EMR) over a wide range of frequencies. In many cases the emitted radiation can be detected at quite significant distances and can be interpreted to reveal the source information. Major sources of compromising emanations include video screens, video screen cables, communications ports and keyboards. A related problem is the inadvertent induction of information into associated power cables. Equipment to carry out a limited EMR attack is readily available at relatively low cost from electronic hobby stores.
 - **Computer information.** Information can be intercepted, damaged or destroyed while being processed within a computer system. Infiltration and interception programs can be written for any computer system and consist of three major functions or phases:
 - Infiltrating the computers—logic bombs and viruses are examples of this.
 - Intercepting or corrupting information being processed.
 - Extracting (if required) the intercepted information.

- **Hidden backdoor programmes.** These are intentionally created vulnerabilities in the form of access programme. The backdoor is installed into a computer or a whole system of computers so that they can be accessed like similar from a room annexed to a whole building. It is an access programme generally called the backdoor. The user doesn't know. This can happen by innocuously downloading software or opening a file for applications, guides, study manuals or simply by clicking an icon that is seemingly harmless. Reputation of the supplier is the only way to know such programmes do not exist in one's system. Backdoors can give access to millions of networks.
- **Access limitations.** Limiting information access limits software vulnerabilities. The damage will be lessened if the user account is compromised.
- **Auto script running.** There are web browsers that will auto run scripts under trust considering they are safe. Standard checks will be pushed aside. Hackers can mimic a trusted piece of code and break into such auto scripts and run malware without the knowledge of the user. The users in such cases will be casual to disable the auto run feature.
- **Bugs trapped in software and interfaces.** There were references to computer bugs earlier. These bugs can be caught in the software at the programme interfaces producing unexpected results.
- **Absence of encryption.** Though unencrypted data may not be problematic, encryption makes it difficult for unauthorised entry unto the cyberspace.

22.4.3 Attacks on Systems

The attack on a cyber system can be from inside or from outside the organisation.

- *Attack from inside.* The major single source of attack on computer systems is from personnel inside the organisation with access to data entry or computer system facilities. Insider attacks in general are both lucrative and successful. The majority of insider attacks are not detected.
- *Outsider attack.* An outsider is someone not working for the department in any way and generally not having authorisation to access departmental premises or computer system. In order to mount an attack, outsiders need to have physical, electronic or software access to the computer. While electronic access is through communications system software access is by covertly infiltration using rogue software.

There are many modes of attack. Insiders can attack through legitimate access to computer systems. Outsiders usually attack by exploiting vulnerabilities in access control mechanisms—the all familiar “hacking”. Other methods of attack include scavenging of information from discarded media, passive interception and covert infiltration such as used by viruses. Any particular attack will exploit specific vulnerabilities of one or more targets: for instance, personal computer (PC) viruses exploit the combination of open architecture design (vulnerability) of the computer system target, ability to modify (vulnerability), application programs (target), lack of

operational monitoring (vulnerability) of the microcomputer (target) and common practice of exchanging diskettes (vulnerability) between systems (targets). The methods of attack will differ from department to department, depending on the sensitivity or classification of the information processed and the departmental computer system architectures.

22.4.4 *System Targets*

As mentioned, a cyber system is a threat attractor. The targets within the system are the following:

- **Information.** The ultimate target in most computer security incidents is the electronic information stored in and being processed by the system.
- **Software.** Software targets include the operating system and the application programs. Attacks that target security mechanisms built into operating system software are of a particular concern.
- **Communications.** As computer systems become more accessible through wide area networks, the networks themselves become targets. Wide area data transmission lines are not protected by physical security perimeters and are, therefore, vulnerable to tapping and disconnection.
- **Equipment.** Equipment such as host computers, input-output devices and data storage media are vulnerable to attack.

22.4.5 *Spams and Spammers*

A computer spam is an unsolicited or junk mail that comes generally in bulk often for commercial purposes. Much of it is sent by botnets, networks of virus-infected computers complicating the process of tracking down the spammers. Spammers are cyber professionals whose identity is concealed but market the products to customers by intruding into cyberspace freely. They are the billboard encroachers. Most of the countries that have advanced network systems, but comparatively less security regulations, attract spammers en masse and specialise in spam exports. That, perhaps, is the height of globalisation! Cyber security is not constrained by national boundaries. Spam is a commodity that nobody wants to import. Many big net companies get seriously affected by the free riding spammers. More than 25% of the junk mails sent across the world in cyberspace originate from one or two countries. This problem is best tackled internationally unless the national cyber authorities cooperate under stringent laws. Spam can endanger the security of the global net. It is a matter of concern for net executives. There are possibilities that spammers team with hackers and virus writers. The explosive growth of spamming shows the slow response of governments towards it.

Spam conveyers rent servers in host countries who allow them for economic considerations. They have the advantage that the advertisements are cheap. They move like other criminals shifting bases when there is a crackdown in one place. Any country with a good IT base and culture can be a host country for the spam migrants. Spammers' modus operandi is simple. They either rent or hijack the PCs without the owner's knowledge to serve as vehicles for transmitting billions of e-mails. There are the Internet service providers (ISP) who have filed suits against spammers. The countries with advanced broadband infrastructure connection at high speed will be the destination of spammers unless there is strong anti-spam legislation. Otherwise spam will continue as the cheapest advertising strategy at very heavy cost to the networkers rather than the spammers by becoming a global blight.²⁶

22.4.6 Phishing and Phishers

Phishing is a fraudulent way of extracting sensitive information under disguise in an electronic communication. The phisher surreptitiously contacts the targets posing as a legitimate individual or institution and lure individuals into providing sensitive data.

22.5 Cyber Security System Providers

Cyber security systems and principles are designed to safeguard data, information, websites, web applications and other system information from various threats that will disrupt, delay, destroy, alter or redirect the flow of data. It is a continuous process in cyberspace. The intensity of threat and the time factor will normally depend upon the motives behind it. Cyber security thereby becomes a critical factor for a government in national governance. It means protection of the computer system and can be done best at national level that the government can be conscious about with the support of system users in cyber security, from organisations to individual users. A national cyber security system is a preferred choice as cyberspace is a terrain that needs to be integrated with other terrains for national security maximisation. Cyber security service is a specialised field of expertise. It has become a constantly evolving industry to respond to hacking, viruses and various other threats to personal and professional data. Cyber security generally covers assessment, protection and remediation of the problem. But at the national level, the best form of security in cyberspace is access denial to those who breach the terrain through unauthorised entries directly or indirectly. This calls for a cyber security infrastructure besides promoting a security work culture among users. The first is technology providers.

²⁶“Spam Jam.” *The Economic Times, Corporate Dossier*, Mumbai. 17 September 2004, p. 4.

The technology profile required for computer system security integration will depend on specific requirements based on in situ vulnerability analysis. In general, the profiling of a cyber system security provider technology and management will include the following:

- (a) Network topology
- (b) Open systems interconnection (OSI)²⁷ reference models
- (c) Transmission media options
- (d) Various types of networks
- (e) Network management
- (f) Various IEEE²⁸ models
- (g) Network administration
- (h) Security of cyber information
- (i) Standards for IT products
- (j) Integration of sensitive networks

22.5.1 Network Topology

Network topology defines connectivity of computers in a network system. It could be in a ring fashion where each machine is connected to a select few in the system. A star topology is when the machines are connected to a central device that may be a hub, switch or any other interface. Another method is to connect to a busbar where all stations are connected in parallel to a single pair of netlines. All these topologies have limitations.

22.5.2 Open Systems Interconnection Model and Network Protocols

The open systems interconnection (OSI) model is a conceptual framework developed by the International Standards Organisation (ISO)²⁹ to categorise the process of communication between computers under seven layers. The model can be used to understand the complex interactions taking place among various devices on the network architecture. The topmost layer is the application layer that describes specifications for the environment. The network application communicates with

²⁷ A model designed by the ISO (International Organisation for Standardisation) to categorise the process of communication between computers in terms of seven layers.

²⁸ Institution of Electrical and Electronics Engineers, Inc. An international organisation that sets standards for various electrical and electronic issues.

²⁹ Also known as International Organisation for Standardisation

network services in the application layer. Application layer protocols have been developed for file transfers, virtual terminals, e-mails, network managements, etc.

Next is the presentation layer, which determines the format for data transmission. This layer converts protocols, translates data, encrypts data and changes or converts the character set. In principle, the layer converts the machine-dependent information provided by an application “A” into a machine-readable form and later reconverted into a machine-dependent form suitable for another application “B”. The third layer is the session layer that allows two applications on different computers to establish, use and end a connection called a session. Once established, there is a need for error-free data transmission. It is done by the transport layer, which provides flow control and error handling. It solves problems concerned with the transmission and reception of data packets and ensures error-free data transfer. The network layer decides the path the data should take. This is determined based on network condition, priority of service and other factors. It also manages traffic problems on the network. The data is transferred across the network in the form of packets and linked from the network layer to physical layer through data link layer. This layer is responsible for providing error-free transfer of data frames from one computer to another through the physical layer which transmits in bits from one computer to another. This layer carries signals that transmit data generated by all the higher layers. It relates the electrical, optical, mechanical and functional interfaces to the cable.

22.5.3 *Transmission Media Options*

Transmission media provides many options from various types of cables to satellites. The choice depends upon considerations of cost, efficiency of transmission, noise signature, installation and maintenance aspects, volume of data that decides bandwidth, etc. While cables transmit data electrically, satellite transmission is through radio waves. A satellite dish or antenna, known as the uplink station, transmits data to the satellite. Transponders on the satellite then repeat the signal, which is received by another satellite dish, known as the downlink station. A major advantage of satellites is the ability to communicate from almost anywhere to almost anywhere else. The bandwidth of the transmission depends on the equipment and number of channels used.

Radio frequency transmission can also be done by terrestrial microwaves. Here the dish antennas are put on top of buildings, as long as there is a clear line of sight between the two dishes. These are short distance transmissions, economical compared to satellite transmission.

22.5.4 *Networks*

Networks are based on applications. They link computers sharing resources. Their typology varies by other usage also. Common networks include local area network (LAN), metropolitan area network (MAN) and wide area network (WAN). The LAN is within a single location, normally a building that houses the organisation and or its associate organisations. A typical LAN is cable connected and managed under an in-house organisation within the location. There is also wireless LAN that uses infrared, laser, narrow-band single frequency radio or spread-spectrum radio. The MAN covers a much larger area and might cover an entire city. But the technology is similar to LAN. Cable television providers use MAN. The WAN is spread over wide areas, such as cities, states or countries, and is a much larger concept than LAN and MAN and different from them.

There are different types of WAN. Some of them are dedicated connections on leased lines providing a point-to-point connectivity between two sites. This type of connectivity is ideal for high-traffic connections. In certain other cases, there are dedicated circuits that are switched on through a carrier network during call setup and disconnected during call teardown. The WAN connections are either through telephones or integrated service digital networks (ISDN). Telephone lines are widely used where bandwidth is not a criterion. The ISDN sets up and tears down connections on demand using the public phone infrastructure. It provides increased bandwidth and allows both voice and non-voice traffic over the same lines.

Another WAN is without an end-to-end physical contact. It is called packet switched connections that use virtual circuits through a public data network (PDN) to communicate with remote sites. They use statistical multiplexing techniques to control network access. This network paradigm enables a more efficient use of bandwidth. These types of connections use two types of standards: X.25 standard and frame relay standard (FRS). The X.25 communication standard defines the interconnection of data terminal equipment (DTE) and data circuit-terminating equipment (DCTE). It incorporates error control and flow control. The DTE equipment comprises computers, printers, servers and transmission routes. The DCTE interfaces the DTE with the WAN. The FRS is similar to X.25 with virtual circuits. It provides high bandwidth as well as the capability to guarantee bandwidth between sites and reduced latency.

There are also asynchronous transfer modes (ATM) for multiplexing and switching that support a broad range of services. The ATM protocol was developed to combine the advantages of time division multiplexing (TDM) and packet switching. It involves conversion of all information flows into short fixed length packets called “cell” (53 bytes). Since it is a fixed length, it facilitates bent wire implementation to result in low delay and high speeds.

There are many factors that go into a WAN solution. Bandwidth is one of the most critical aspects. Others are service availability, cost, manageability, performance-monitoring capabilities of the system, maximum traffic, reliability, quality of service, accessibility and security architecture. In addition to area

networking, there are also requirement in today's world for mobile computing. It is a technology that enables people on the move to remain connected to a computer network including their own personal computers. This type of network employs telephone carriers and public carriers for the exchange of signals. The transmission is made packet radio communication, cellular networks or microwave systems.

In addition to the common networks, there are other networks too that may link with one of the common three. It is a matter of naming by users based on choice and cyber convenience. The network will comprise an array of computers, servers, mainframes, peripherals and devices to allow the sharing of data. A universal example of network that can be easily appreciated is the Internet.

22.5.5 Network Management

As mentioned a cyber network is a collection of individual computers and components working in system harmony. Network management helps maintain the harmony, ensuring consistent reliability and availability of network, as well as timely transmission and routing of data. Dedicated devices are important requirement in accomplishing network management by host computers on the network, by people or by combination of both. Network management includes network monitoring, control, trouble shooting and statistical control.

The performance of network is typically judged by comparing it to acceptable service levels. The service levels are based on the availability of the network, reliability, response time and throughput. Throughput is the measure of network transmission speed based on the net bandwidth of the network. It is a measure of number of information bits per second that can be accepted and transmitted by a network.

22.5.6 Network Administration

The network administration is the work of a network manager. The network manager is responsible for managing user accounts, configuration and control for network consistency, change management, media management, network security, disaster recovery, data backup, information audit, maintaining audit trails and verification to avoid fraudulent use of the system.

22.5.7 Integration of Sensitive Networks

Integration of sensitive networks may be important, but it is not advisable to integrate them till the importance is established. There is a tendency among

policymakers just to decide an upgrade in management by doing something that others have not done. Such executive behaviour pattern can affect security aspects, if not done thoughtfully and after very critical examination. One of them is sensitive organisation integration. In such case, integration can dilute the sensitivity since the sensitivity factor of two organisations may not be exactly identical. In such cases what one has to do is to raise the level of the lower one to equalise with the higher one or integrate only equal level sensitivity factors of each organisation and that too if it is really required. This has to be taken up anyway by the respective organisations. The network obviously shall undergo vulnerability analysis once the decision is taken to integrate. The security grading of the networks should be assessed and formally promulgated. The security policy is to clearly specify the gateway protocols and the security overlay for the integrated networks.

22.5.8 IEEE Models

The IEEE models are developed for LAN to help define LAN standards. This model defines the network standards for the physical components of the network, the network interface card and the cabling, which are defined in the physical and data link layer of the OSI model. There are many specifications.

22.5.9 Security of Cyber Information

The standard guide for policy for the security of cyber information is ISO-107799. The policy is aimed at securing cyber assets that contain information. The policy sets out rules and guidelines for the organisation on how to approach the issues. The policy should guide an implementation plan. The attributes of a policy statement are to be decided by the organisation itself at higher level of management. The policy should deal with the concepts and classification of cyber information. The policy may cover all aspects of cyber security, which broadly will include the following:

- (a) Security practices
- (b) Cyber ethics
- (c) Password policy
- (d) Software policy
- (e) Network policy
- (f) Internet policy
- (g) Email policy
- (h) Website (organisational) policy
- (i) Policy on laptops and portable computers
- (j) Security policy for desktops
- (k) Help desk support to security

The computer and network policy will widely cover the system administration policy including physical security, access control, network policy, disaster recovery mechanism, application of the security policy, audit, software development policy and documentation procedures. Over and above a minimum security criterion, important components of security overlay that could typically be used by the organisations in their networks are firewall, perimeter defence and intrusion detection system, security audit systems and encryption mechanism. Encryption would be required to render the information unreadable to unauthorised users or eavesdroppers. The exact specifications for the overlays will need to be evolved after undertaking vulnerability analysis. Other methods are antivirus protection, critical data backup, access control, user classification, multilevel secure systems, biometric and other methods of authentication, encryption and decryption of data, spyware protection, etc.

A cyber system that needs to be protected should undergo serious risk analysis for identifying the assets to be protected and potential threats against them. Performing an accurate risk analysis is a vital step in securing an information environment. A formal risk analysis answers various questions related to the assets. The security system is obviously followed by an audit team and response emergency team for disaster recovery and assessment. The security policy is to clearly specify the gateway protocols and the security overlay for the integrated networks.

22.5.10 Standards for IT Products

The standards for IT products are vital for data security. It is an area that will be overlooked at times. The organisation should draw out the standards and maintain the repository. The standards have to be evolved by expert consultation.

22.6 Cyber Laws and Jurisdiction

Cyber security is an element of national security, the optimisation of which for the overall national security maximisation is one of the governing charters of the government for which it is accountable. It operates in an exclusive terrain. Establishing rule of law in the cyber terrain is one of the tasks of the government. In this process the government needs to establish cyber laws to secure and safeguard the terrain to support the elements originate from there. Laws related to cyberspace or cyber laws, therefore, forms the crux of the rule of law in regard to cyber governance for a country.

Cyber law modifies cyber behaviour of people engaged in the technology and governance of cyber systems. The domain and scope of cyber law, also known as cybercrime law among certain groups, is vast and progressive. This study recognises the topic as cyber law in singular with various cyber laws within as and when

legislated as part of it, where cybercriminal law forms a part with various criminal laws within. Therefore cyber law is not cybercriminal law. It is taken as an umbrella term for the rule of law in cyber terrain. It is also important to know that the rule of law in cyber terrain may also be supported by other enforcement-friendly laws available internationally and nationally (domestically) in various other terrains.

One of the issues related to cyber security is its jurisdictional aspects. How does one react to information in the web that is libellous or incorrect? Internet users and supporters may find a lot of libel material and hate mails in the system besides incorrect information. Such distortion of communication does not happen in any other media. The Supreme Court of Australia gave a verdict in 2002 concerning Internet defamation jurisdiction. In a case “Dow Jones vs. Joseph Gutnick”, it was held that a defamation arising out of a story on a US website can be heard in Australia. Dow Jones operates a website called www.wsj.com, a subscription news site operated on password given by the Dow Jones. The edition of Barron’s on Line for 28 October 2001 contained an article entitled “Unholy Gains” in which several references were made to the respondent, Joseph Gutnik. Gutnik brought an action in the Supreme Court of Victoria, Australia, against Dow Jones claiming damages for defamation. He claimed that the article defamed him by portraying him as a schemer given to stock scams, money laundering and fraud. Dow Jones argued on jurisdiction. The court held that the law of defamation seeks to strike a balance between, on the one hand, society’s interest in freedom of speech and the free exchange of information of ideas (whether or not these ideas or information find favour with any particular parts of society) and on the other hand an individual’s interest in maintaining his or her reputation in society free from unwarranted slur or damage. The judgment further held that the Internet is no more ubiquitous than some television services. It was held that those who post information in the web do it knowingly that the information they provide will be available to all and sundry, without any geo restrictions.³⁰

There are issues, though. One is enforcement. Another is conflict with the emerging jurisprudence with jurisdiction, because of different laws in different countries. The judgment can affect not only freedom of speech of media organisations but also expose publishers all over the world to legal actions. The global nature of the Internet may be undermined by some publishers masking the readership in other countries for articles and news. There could be again localised decisions where a law court may not agree for enforcement of the verdict of another court in another country.

It is only natural the world of free web becoming a space for racist propaganda and hate campaigns. Paint-smeared worship places, abusive languages against different ethnicity and inciting for hate attacks are all there. Purveyors of hate can find a potent tool in the Internet. They can spread fear by showing horrendous acts against humanity. Online games allow children to shoot under racist propaganda. There are recruitment sites for terrorists and mercenaries. There are political party

³⁰Duggal, P. “E-slur Here, be Sued There.” *Hindustan Times*, New Delhi. 15 December 2002. p. 12.

sites that promote racism. The dilemma is that the Internet is global, easy to use and tough to regulate. Intellectual property rights can be violated, and terrorist attacks can be plotted through the Internet. There are no easy solutions in cyber security. Better coordination between governments and Internet service providers may give a chance. It was reported that there were 4000 racist sites in the world in 2002, and more than 50% of them were based in the United States.³¹ The ultimate threat attractor in the cyber terrain will be privacy of the individual—the cyber paparazzi are already around.

22.7 Crime, Espionage and Warfare—Cyberspace

Cyber terrain opens up opportunities to spy stealthily on the national security apparatuses of a nation. On 20 April 2004, the information minister of India made a short mention about an alleged Chinese business attempt to spy the security apparatus of India. The Union Cabinet was briefed. The announcement was made in Rajya Sabha (Upper House). The Indian intelligence agencies, Intelligence Bureau (IB) and the Research and Analysis Wing (RAW), found evidence to suggest that an Internet start-up drive circulated among some Indian agencies by a business house with Chinese links contained an embedded programme capable of penetrating computer hard disks. The programme was apparently also capable of diverting all cyber traffic from the computer system to an unknown server. Such methods are common that certainly may not be restricted to just one country alone but almost all who have cyber capabilities. For this and other reasons of vulnerability, information security is the buzzword in cyber security. According to statistics, 300 viruses are released daily into the Internet (2004).³² There has been an increase of 52,000–82,000 hacking incidents, according to a Carnegie Mellon study worldwide.³³ Companies and organisations pay good amount for cyber security. For the same reason, cyber security has grown into a critical business enabler and an investment by itself.

The dangerous and illusory saga of virtual reality is emphasised by the story of a 14 year old that lured his Internet buddy into murdering him. It was brought to the attention of a court in Manchester, United Kingdom, that left the web people horrified. It was a spy spook he masterminded with characters, interchanging roles under false identification. The spies instructed the buddy to murder the originator, stabbing him with a big knife. For that he would be rewarded as a full-fledged British secret service spy, to get to meet the prime minister and half a million pounds in cash. It was a plot so bizarre and unheard of in mind control. That is the pace for

³¹ Keaten, J. 'Will US Join Europe to Fight Web Racism?' *The Economic Times*, New Delhi. 18 June 2004. p. 20.

³² Rumu, B. "Under the Scanner." *Hindustan Times*, New Delhi. 19 May 2004. p. 10.

³³ Ibid.

surreal story telling in cyberspace. The community believes that unmonitored Internet chat is at fault. But that is only one such thing in cyber world where flights of fancy can become reality crimes. Cyber security holds the key. Cyber terrorism is a new word that will find a place in cyber security. Buttressing security walls is important. The number of security incidents today are increasing multifold to an alarming 137,529 in 2003 compared to 82,094 in the previous year. It was 1334 a decade before.³⁴

Hackers play serious roles in cybercrimes and cyber warfare. Hackers are not criminals, just like the way anyone who shoots is not an assassin. Hackers are brilliant cyber scholars who have all the time to spend in front of a computer intelligently that others may find boring and cross-eyed. This is a preferred definition just to drive home the difference, because a hacker is a useful warrior in cyber warfare. Hackers are respected for their wide array of knowledge in computers. Hackers get into a bad phase when they want to gain publicity and “do something big and difficult” that too quickly. They crack into systems and cause havoc normally for no reasons. Hackers can be well used for cyber warfare.

While computers support warfare to the maximum today, the predictions are that soon computers will be the weapons in a war. The conventional warfare concept will be the trailing edge with the silent, invisible and deadly weapon systems run by computers in information warfare in its peak. Information security is essential to counter cyber warfare. Nations looking toward invincibility is on the search for newer hardware that are smart and cyber controlled.

22.8 Cyber Terror

Cyber terror is another term which security fashionistas may use to explain. . . what, terror in cyberspace? In strategic thinking and process, it is important to define the terms as mentioned earlier to avoid semantic dissonance. Terrorism is a crime committed by the relatively powerless in which people get killed and properties and environments destroyed. They create mayhem that will induce fear in people. Terrorism is more a psychological nuisance than a freighting challenge at the level of governments. A state is more powerful than any terrorist. Terrorism is diffusing slowly in the world compared to olden days. Loss of life, property and environment also happen in a disaster scenario. Disasters can also be induced by human actions. So, terror in cyberspace can be any unlawful act that has to do with creating a terror situation directly or indirectly by breaching cyber security. Or it could be an act of terror that uses cyber terrain for causing it. However, it depends upon how the cyber law defines cyber terror. In standard definitions, cyber terrorism is the use of computers or computer systems to conduct acts that can be defined as terrorist

³⁴Sridhar, V. “Info Security Blanket Has People Holes.” *The Economic Times*, New Delhi. 31 May 2004. p. 5.

acts. The terrorist activity is generally for specific gains or as an act of psychopathic distress. So there is **a convergence cyberspace and terrorism**. What is common in any such case is the affiliation of the act with breach of cyber security. The national policy of cyber security can cover such unlawful acts as a matter of law enforcement.

Computers can be used as a weapon or target in cybercrime. Computer and its associated space is used as a weapon to commit crimes in real space and time. Cyber terrorism is one such crime along with fraud, intellectual property rights violations and other crimes. Cyber terrorism to this extent is a larger conflict domain.

22.9 Artificial Intelligence

It is necessary to know that human intelligence cannot be made or created artificially, at least for now. Under this lemma there is no other “intelligence” comparable with human biological intelligence. This also means under no circumstance human intelligence will become inferior to anything called “artificial or electronic intelligence” as it would have been made or created by humans in the original instant. Artificial intelligence (AI) or electronic intelligence (EI) as some prefer to call it cannot be compared with human intelligence (HI). This is important to understand in this study.

AI is the name assigned to programmes in electronic neural networks and systems that operate independent of human intervention. It is a commercial term, and there is no objection to call such programmed intelligence artificial. Expert systems and artificial intelligence allow people to use their computers in a variety of new ways and also pave ways to robotics and nanos to perform jobs that are difficult for the humans. All these originate from HI. Expert systems and AI are certainly revolutionary designs of the cyber world. Currently their use is within business corporates, scientific establishments, hospitals, military and similar advanced and complex fields. Expert systems show the way to do what they do, in a better way.

AI, as it is known widely, opens new vistas for scientists to experiment new things the computers or cyber systems can perform. Among them, some focus their work on the AI towards human intelligence and cognition. Such computers or cyber systems recognise human voice or picture by translating texts from one language to another, a technique that will be of immense value to robotics. AI therefore forks into creating intelligence that can match human intelligence and using intelligence that the system can take on more without human intervention. The former may end up as a mere desire since human intelligence is a biochemical mechanism, whereas artificial intelligence is strictly electronic. Humans are yet to enter the world of biochemical energy engines and machines seriously. It is not known whether there will be computers with biochemical chips or a car that sweats and pulls up on its own to visit the rest room for a leak or park itself on the side to cool down when driven under duress. Well, in such cases, naturally another terrain will pop up in the national security map, not just an element.

AI today is quite advanced. Its commercial world comprises many avenues that include robotics, human languages, design and development of better human interfaces, developing larger applications and more widely applicable expert systems. Robotics, perhaps, is the finest species of electronic intelligence designed to help humans in astonishing ways and in situations and locations beyond human capabilities and reach. The robots carry electronic “intelligence” in their “brains”, wherever they are located. They are no more restricted to science fictions, cartoon strips or fantasy movies, though most of the sophisticated ones are still confined within them. Human language is not just neural language modification. The AI research permits computers to interact with people on their own natural language domain. It is just meeting and conversing with people in their own language. There will be more cultural compatibility in human-computer interaction with the development of natural language. By developing psychological and special programming techniques, there are possibilities for better human interfaces to make computer user-friendlier. It is a continuous process not just driven by urge for innovation but also by competition. Developing larger applications by using AI techniques is a commercial possibility that may include even new programming languages. This will also lead to automatic programming in which an AI computer will develop a programme. Expert systems control the smart key in AI. It has received good acclaim commercially and, therefore, has high probability in advancement as an AI tool. Expert systems can perform highly specialised tasks as effectively as human experts.³⁵

Expert systems and AI are no more confined to the laboratories. They are out in the open commercially. There are no problems as long as the robots are not designed to kill. But in the future, they could be. Speculation has no place in human history. Threats have to be perceived on reality factor, not under paranoid frenzy. That is why national security has to be based on principles and absolute pragmatism with reality as the cornerstone. The problems can be solved if the concept is practically analysed even before they happen. That is problem-solving in its correct perspective.

The ideas from the AI are expanding. It deals with representing new knowledge, heuristic (rule of thumb) search and separation of knowledge from inference and control. These ideas have place in knowledge world today. It may lead to non-programmer programming a reality. There also lie speculative dangers. Decision-making under uncertainty and other situations when information is insufficient is what the support AI can give to organisations in a heuristic manner.

³⁵Harmon, P., Maus, R., and Morrissey, W. (1988). *Expert systems: tools and Applications*. John Wiley and Sons, Inc. pp. 4-5.

22.10 Cyber Policy

Problems associated with cyber security have become even more critical and challenging since widespread adoption of the Internet and the web. The Internet has made computers across the globe interconnected. Despite the convenience of data sharing and information exchange, the Internet has also become the major highway for computer viruses to travel on. Instead of infecting one computer at a time by spreading the virus via floppy diskettes, the attackers use the Internet as the transmission channel to spread their aggressive agents. Thousands of computers and networks can be in peril by Internet attack within a short period of time. Confidentiality, integrity and availability of information are integral to cyber security, which requires access control, authentication and non-repudiation to prevent breach.

Networks with their generative computer array are critical to administrative and operational activities of the system. Security could be compromised when flexibility factor is imperative for information flow. Flexibility in operation means probable security risks. Protection means flexibility sacrifice and information blockade. Both ways it is a question of balancing the system between flexibility and security. That is the core of cyber security. Developing security package continuously is, therefore, necessary to meet fresh challenges to security. Cyber security, therefore, is a constantly evolving field and runs concurrently with system development and advancement. It is integral to its evolution, though caught up lately. Still, the cyber world is at great risk.

A cyber security policy statement calls for effective system administration by experts in the field with high-powered access control at all stages of information flow. It can be achieved in many ways appropriate to the system devised by the administrator. It is based on the capabilities available to the administrator. At the national level, the policy statement should include access control modalities and legislative measures appropriate to the sensitivity factor of different information. To that extent cyber security is closely linked with informational security. The Internet, while serves as the information lifeline in the modern world, its two-way approach and inherent weakness make it highly susceptible to cyberattacks on the other. The Internet is an open disclosure of information even at the highest security level today. While it is the longest penstock for information flow that can provide power to decision-making, it could also pulverise the national security elements that depends on it for information. The types of attacks vary and new methods are evolving. Therefore, the system design for security also needs to catch up with the dark forces at least if not ahead of them. It is a question of cyber personnel against cyber-induced technology algorithms that calls for constant upgradation of personnel protocol, network security, user awareness, server security and database management.

The cyber domain is a boon to transnational and national criminal syndicates and militant operators besides those involved in information trafficking, insurgency, espionage, sabotage and subversive activities. It is easy for critical information to fall in their domain and seriously compromise national security. The cyber medium

is the fastest and an inexpensive facility. Therefore, an effective and compatible security policy is the basic need for any cyber system administration.

22.11 Cyber Advancement and Transformation

Has the world seen it all in cyber technology and development? From the abacus to cybernetic principles to cyberspace inside a chip was seemingly an amazing journey of human intellect in transforming life that may surprise humans themselves. But this study feels that cyberspace is just a turn in a direction that is going to take humans to a never-ending cyber galactic odyssey in the course of extremely measured time. What the world witnesses today is, perhaps, not even the beginning of cyber concept and technology from the standpoint of the possibilities of human intellectual advancement in both good and bad applications of cyber science and technology in life.

Good and bad are relative expressions. Humans consider good as constructive and bad as destructive. But construction cannot exist sans destruction. Therefore destruction is not opposite to construction. It is “ante” to construction. Well, the author is not sure. . . For example, matter “exists” in space. Space is appreciably formed in the creation of matter by time. Move matter, space appears, like the table top becoming visible when the dust accumulated on it is wiped off. It was detailed earlier in the description of the sandcastle and the moat around it. But can space have energy? Because the matter that is energy is already moved to create space. Well, that is what humans believe. So, humans use the term negative or black or grey or, if digital, adding too many zeros to the starboard (right)³⁶ side of a digit. . . or “anti” as the author mentioned in this study “ante” cleverly attempting to conceal his bottomless ignorance on matters that he is not sure about. . . Limitations galore in human intellectual life. . . Pushing it forward is a natural phenomenon by default that keeps the machines of life ticking. That will be experienced in every terrain of national security, because it is a human subject. Humans are in a never-ending quest of that moving target—well-being. Imagine what Jason would have done if the Golden Fleece moved every time he moved towards it equidistantially! The story would have never ended like some of the TV soaps.

More so, what is good for one may turn out to be bad for another. So, the phrase “good can destroy and bad can construct” in reality perception is based on this reverse ideology. Psychologically one of the presumptions is that the purpose of invention is destruction in a mindset deep rooted in survival. All these means there is only advancement, not retreat for human intellect and all matters associated with it—yes, good and bad, nothing ugly, though. That is ideated as surging in human system according to this study. The surge theory was also mentioned earlier. Up to where and how long will humans advance? This too can be answered if the principle of

³⁶The shippy term for right. Isn’t governance a nautical term about driving a ship?

moving targets or equidistantially³⁷ moving target is taken into consideration. This will be clear if advancement is taken sans its good and bad applications considering the terms relative to human appreciation. If life forms are indefinitely infinite, then the process of their dynamics into time will be frustratingly slow. This is what cyberspace may experience—tardiness under certainty of advancement. So, don't be in a hurry.

Well, all these are not just arguments, but expositions to various arguments on advancing and transforming cyber matters in the cyberspace. The subject has bloomed well and transformed the world in many respects even in this primitive stage. At least it has unified everything, warts and all, in the human systems. The good and the bad of the world have an opportunity to equally exploit the cyber revolution. Remember what Norbert Wiener felt about cybernetics? He felt guilty based on assumptions (Box 22.3). He didn't have to. That is quite common among those who want the world to be good for all like this study on well-being. But they want it to be good in their exclusive ways. Some of them regret advancement based on self-apprehension. It happened to those dealt with nuclear research, dropping the then called atom bombs, space technology, etc. The author vaguely remembers the pessimism expressed by Sir C.V Raman, the Nobel laureate in physics, saying that the world would be doomed after the then Soviet Union shot the first space craft "Sputnik-1" into orbit on 4 October 1957. He was partially right. The world can now use space to kill people on earth. Any advancement in technology has its duality of constructive and destructive posers as choice to the humankind, and the results are accrued by all. But this study looks at this duality as singularity. That's why humans need governance for well-being. And they are designed for survival only by cooperative behaviour and collective governance using the tool of intellect. But the tool can cut and injure if not used under right discrimination. The concept that leads to this well-being is national security. But there will be insensitivity to a development after certain time when it peaks. It has to be curved by governance.

Box 22.3: Norbert Wiener Was Not "Very Comfortable" Introducing Cybernetics

Norbert Wiener (1894–1964) concluded that he and others were not very comfortable in introducing cybernetics because it could be used for evil, though there was a good part to it. He had a slight hope that cybernetics would be used for human good. For the author, Norbert Wiener didn't understand at that time he and others were not introducing a mere topic but leading humans into a new terrain.

³⁷Equidistantial is a noun. It is explained in non-Euclidian geometry. A curve, in Bolyai's non-Euclidean geometry, coplanar with a straight line, perpendiculars to which from all points of the curve are equal.

The cyber world, perhaps, has not yet offered even its lowest potential package to the world. It is only a matter of time inventions and pathways that support development today are viewed as primitive tools by generations in future. Human advancement is on the fast lane, and of course parallel to it is its decline. But development in every field may have to be a process that will extinguish only when it reaches its peak value. Cyber world perhaps have not even seen its introductory heights least to mention about its peak value. Biochips from the simple garden spinach to the most resolute robots that may never think of hurting another robot least a biological life are yet to come. The world is waiting.

A curtain raiser in support of this argument is nanotechnology that is poised to revolutionise the cyber world. Nanotechnology deals with the “small by miniature design” and is a fast-developing field that may revolutionise changes in life, if successful. It is through nanotechnology scientists believed that spinach cells may one day power (a la Popeye)³⁸ laptops, cell phones or bio pacemakers. It may revolutionise the cyber world and associated fields of human life. Smart houses, offices, malls or anything where a tiny nano-chip can make a difference will brighten up activities. Nano-technology will shrink machines. Doctors may have the entire laboratory for diagnosis inside their pockets in the shape of a chip made by molecular assembling even by replication. The possibilities are amazing. But the subject is yet to develop. Once it develops, it could detach from cyber security or genomic security. There could be intelligent nano-devices inside the human body for immunisation. The field is yet to see its greatest achievements in steering human life to dizzy heights demanding more from governments in terms of security requirements.

The field of quantum computing is new and relatively much advanced. Quantum computing will upend everything what the classical computers do today by the quantum phenomena such as superposition and entanglement.³⁹ Quantum computers can handle information differently from the present methods. They shall outsmart the present-day supercomputers. Such computing is necessary to tackle special problems that the humans are going to face in their advancement.

Quantum computing is not just a name. Quantum computers use the properties of quantum physics for storage and computing. They are based on quantum theory. Quantum theory explains the behaviour of matter and energy at atomic and sub-atomic levels. The quantum bits called qubits are different from the binary bits used in classical computing. They have both superposition and entanglement that will permit a quantum computer to calculate with many complex variables at the same

³⁸ Popeye the Sailor is a fictional American famous burly cartoon character, created by E.C. Segar. Popeye derives strength from a can of spinach.

³⁹ Superposition is essentially the ability of a quantum system to be in multiple states at the same time. Superposition is one of the properties that allow the quantum computing paradigm to supercede classical computing. The other is *entanglement* which is a necessary ingredient of any quantum computation that cannot be done efficiently on a classical computer. Superposition and entanglement are quantum phenomena. Quantum computers use the to perform computation.

time. Though quantum computer has been ideated half a century ago, they are becoming a reality in a phased manner.

A step ahead is live computers with human bionic chips.⁴⁰ It is not clear whether they will be called chips by then. How about biomeres that empower bionic computers? Every such bionic computer may have biomeres a la telomeres for processing and upgradation. Thought processes are underway to replace silicon chips architected with human brain cells. The idea is to harness the power of the actual brain cells to power the next generation of computers. That will not only bring the computers in a bionic mode but also may give a (dangerous?) morphological twist to the whole concept of artificial intelligence. This may sound a difficult prospectus. That can make neuroscientists as the new cyber people. There are many possibilities for human bionic chips or biomeres if succeeded. The steps are too short towards biological computing at the moment, but the world is certainly edging in that direction without losing hopes. There is much hope among scientists and technologists in their attempts to make the cyber world a bionic terrain. According to a report, there are three major hurdles the scientists will have to overcome to transform the cyberspace from silicon to cellularly bionic⁴¹:

1. How to structure the neurons as in the human brains?
2. How to write and read information in single neurons?
3. How to keep the neurons stable?

This is what the scientists are up to. There is no reason to believe they would leave it, especially under extreme neural energy to overtake the competing humans, come what may. Stephan Hawking had once mentioned that artificial intelligence would take over humans and end their kind.⁴² This book had denied it elsewhere. But the denial may find difficult to survive as Hawking should know better and looking at the cyber craze for making it live. Bionic computers could be in the offing to take over from the silicon generation. It will be a jump over a span that is many times longer than fire to farming in human history, though, but certainly the next step in human advancement.⁴³ If that happens it is quite possible for humans to jump from fire to frying pan calling Geronimo or something similar for the last time. The maximum humans can do is to understand it early. One of the questions the author has been toying with is whether the terrains of genome and microbiome will merge in the future in the national security perspective. But after detailing cyber security in

⁴⁰The term bionic chips are used to explain the microprocessor if made from human brain cells or any other living cells that is capable of performing several functions faster than human brain through a singular bionic processor that may also grow in capacity based on demand.

⁴¹McShane, S. (2016). "This Amazing Computer Chip Is Made of Live Brain Cells." <https://singularityhub.com/2016/03/17/this-amazing-computer-chip-is-made-of-live-brain-cells/>. Accessed 15 January 2021.

⁴²Cellan-Jones, R. (2014). "Stephen Hawking warns artificial intelligence could end mankind." <https://www.bbc.com/news/technology-30290540>. Accessed 18 November 2018.

⁴³Various steps in human advancement that this study supports are fire, farming, industrial, communication, cyber and genome.

this chapter, there is a serious doubt whether the merger will be between cyberspace and genome the genomic space. That means the sands of the present-day computer world may return to the beaches, and silicon valleys may turn out to be neuron valleys.

22.12 So, What Is Cyber Security?

Cyber security, in this study, is the 14th identified element of national security in the chronological hierarchy of 16 elements. Cyber security, “cybersec” in short with the symbol “c_s”, is about managing and governing the cyberspace, the sixth terrain of national security to the best advantage of the country and thereby to the people. It is not cyber security, the commonly termed cyber system security, the security of the computer space and information, but a whole element of national security that needs governance in tandem with other elements for maximising national security.

Cyber security is the only element in the terrain of cyberspace for now. Therefore cyber security as an element of national security is the lone sentinel to cyberspace with applications in all the other terrains. It is vital to information technology. Cyber security that deals with security of data and information in the cyberspace has a different outlook from the domain of cyber security, the element (Box 22.4). The former is a term used for securing information. Cyber security, the element, envelops cyber security, the exclusive privacy of information.

Box 22.4: “Cyber Security” Is Not Cyber (Systems) Security

“Cyber security” as an element of national security in this study is not cyber security, the term used for protecting information, which is also known as information technology security, which is about the security of cyber systems from information point of view. The latter is part of cyber security, the element.

One of the major election processes in the world was the presidential elections in the United States in 2016 and the highly contrasted next episode of it in 2020. The results in both surprised some, welcomed by some and pretentially as well as prudentially shocked a lot but throw light into cyber security governance seriously in national governance. The elections for the President of the United States (POTUS) will make a great study not only in cyber security but the entire national security concept itself of things that are there and going to come in human advancement and transformation of governance. The waves related to the elections that are going around the cyberspace are still unsettled. The author calls it the PT⁴⁴ syndrome in national security strategy related to governments. The PT syndrome was there since

⁴⁴PT is not an abbreviation or an acronym.

not only the days of the ancient Greek governance but also in the ancient Indian epics dated much earlier to the former. These are mentioned here just within the limits of the topic on cyber security (Box 22.5).

Box 22.5: So, What Is PT Syndrome?

PT syndrome is a term by the author. It is about taking advantage of a situational human system process by “chance farming” by those external to it. This type of chance farming has been there in the world since the beginning of reason. A governmental election is an occasion for chance farming. Every nation and associated authorities were in one way or other interested about governments in another. The alleged Putin-Trump engagement in the two US elections is just one of them if true.⁴⁵ But the difference is the involvement of cyberspace. This is mentioned here as the PT syndrome that is exclusively to differentiate cyber security governance from cyber systems security management. The term can also be applied to all fields of political “chance farming” in governance.

22.12.1 Definition—Cyber Security

Against the background of this study, cyber security means *the capability of a nation to manoeuvre in its cyberspace at will in absolute freedom in matters related to its national security governance, safeguard the data, secure information including intelligence, protect and integrate the cyber terrain along with all that it contains, perfectly aligned with the other elements of national security and integrated with all the terrains of national governance.*

22.13 Summation

Cyber security is a national security element that needs serious attention of the governments and the lawmakers. It is not sufficient if the government is interested only in securing the cyber highway concerning it. This is the natural attitude today. Citizen’s matters are left to the individuals concerned. It will be a grave mistake that will be realised by the governments at the most inappropriate time—when maximum damage is done. Cyber security as a national security element in governance has to have the deserving position in governance by national security. It is not just about the security of the cyber systems including information and information highway. It is

⁴⁵“Joe Biden says Russian President Vladimir Putin will ‘pay a price’ for meddling in US election.” <https://www.abc.net.au/news/2021-03-18/biden-vows-putin-will-pay-a-price-for-election-meddling/100015608>. Accessed 18March 2021.

about using cyber systems for governance. There should be stringent national and international policies in cyber security matters. The problem for incompetent governance is that none of the elements of national security are mutually exclusive. They are all interlinked. Therefore they have to be optimised by themselves and through terrain integration by competent governance for maximum well-being.

While cyberspace is a gold mine for knowledge, it is a dangerous place for national security initiatives. One such danger comes from antidote writers and diagnostic companies who need hackers, virus writers, worm creators and spammers to flourish, because it indirectly supports their business. This makes cyber security a special field in a special terrain where surveillance and monitoring have to go together with appropriate control measures. The problems faced are data mining, aggressive advertising parasites, scumware, keyloggers, viruses, worms, bugs, dialers, malwares, browser hijacks, tacking components, destructive tool kits, etc. Cyber security governance will require laws, rules and regulations tailor made for it under international and domestic laws.

Designer viruses and spywares are the orders of the day. They are the specialised ones that can steal just what they require—the data of the adversary. An outbreak called “scob” was designed to steal financial data from computers and passwords in June 2004 worldwide. It exploited certain vulnerability in servers using a version of particular software. It was a potentially dangerous virus. The infected servers in turn exploited the vulnerability in the browser to install a Trojan horse virus on the PCs of web surfers who visited the infected websites. All these happen when one is viewing the same page. Without the surfers knowledge, parts of the browser were already redirected to another website. Even the most trusted website may contain potentially malicious codes. There are more (Box 22.6) that may make the governments to sit and think about such systems that could be used by or against them in the complex cyber terrain. In a cyber terrain, everything is penetrable even the one used to penetrate. There lies the catch in governance of cyber security as an element of national security.

Box 22.6: Pegasus: The White Stallion that Came Flying

In Greek mythology Pegasus was a flying white stallion, one of the sons of the Olympian God of the sea Poseidon. It had supernatural powers. But the Pegasus, the spyware that hit the world in July 2021, embarrassing many governments, was not winged like the mythical stallion but equally mobile, powerful and mysterious. It was a highly sophisticated spyware created by the Israeli cyber intelligence company NSO group. Pegasus “could fly and infect” android and iOS phones and covertly clean them up of information for the client covertly. Under the company contract, authorised customers (governments) are required to use Pegasus only for criminal and national security investigations without violating human rights.

According to an Internet security technologist, the only secure computer is one that is turned off, locked in a safe and buried 20 feet down under in a secret location. He also adds that he still is not confident about that either.⁴⁶ Well, another safe computer may be the one that is smashed under a military tank. But the facts are clear. The cyberspace is vulnerable and along with the governing system. Cyber terrain is expansive and unlimited unlike geophysical terrains. It is getting harder. Privacy and security have become virtually impossible unless stringent measures and vigil are imposed. Cyber laws are at nascent stage and there are no serious cyber cops to enforce them.

Cyber governance or e-governance as called generally has become a regular practice in global governance. The Covid-19 pandemic accelerated cyber governance globally. The world could easily adapt to forced isolation under pandemic quarantine and adapt to the changes without serious discomfort even deviating into advanced modes since 2020. The advancements in governance are not likely to retreat. Cyber governance received a boost from the 2019 global pandemic discomfiture. World governments could handle scenario in an entirely different way from the practices and troubles they experienced since the first known pandemic about 5000 or so years back (Chap. 14). The human system understood the advantages of cyber governance very clearly. It is left to the respective governments to plan and execute it with a global concern on matters of cyber security element.

Though snooping on one by another has been an age-old practice, cyber security governance by government using spywares even if legally contracted and ethically programmed can be counterproductive when public realises that one's computer system can turn into a spy for the adversary who could even be a contractual client to the tool provider. This is a governance issue in cyber security governance and perhaps the most revealing one that indicate serious impending changes in the cyber terrain and the element of cyber security in the near future.

23.1 Introduction

Identifying a concept or an entity in its right and clear perspective is vital for knowledge generation and knowledge retention. Thereafter it leads to knowledge regeneration. It is most axiomatic when the subject of genetics is discussed. No other discipline surpasses genetics in mystery, awe and mix-up. It is one of the frontier elements of national security in a terrain of its own today—the genome (Chap. 6). Similar to cyberspace holding cyber security as a unitary element of national security, the genomic space holds genomic security that has implications to the entire process of life in which form it is. This can change in the future. Genome is life and the only living thing that knows about its existence is the sapien of the day.

In the beginning of the twenty-first century saw humans at an unusual fork of their intellectual movement. It was a turning point in their lives of the past 2.8 million years or so, or whenever it was, when the first human bipedal walked on earth.¹ Whether it will lead them to attain the capability of reading themselves and other living organisms like a book or an astrodynamically² charted genetic horoscope and solve the mysteries of creation for the future generation or destroy them totally once for all by their own intellect and wizardry gone berserk will depend upon the road they follow from now onwards. Genomic research and its application to life are poised to be the next revolution in the insatiable thirst of the humans for knowledge gathering and experimenting like making fire with stone, wood and tinder—yes, also blowing on it. The secret may lie in the critical frequency (speed) of advancement in genomic studies.

Genomic studies have the potential to revolutionise every other branch of knowledge. Yet, things can go wrong in this process. The psychology of inventions and dexterously heraldic creations can at times resonate with notes of destruction. A knife can cut what is not necessary. Surely there are many surprises in stock that may make or even break the future of the inquisitive humans.

¹There are many research findings. According to BBC News, “First human discovered in Ethiopia” (Pallab, Ghosh, 4 March 2015) was 2.8 million years ago as concluded from a jaw bone. <https://www.bbc.com/news/science-environment-31718336>. Accessed 13 November 2020.

²The term *astrodynamics* is used by the author for the study of astrological clarity and mismatches under the principles of falsifiability which could be examined phenomenologically and as a time functions with reference and way points similar to a tide table or navigational or pilotage bearing points, deduced from calculated events, or a normal timetable of planned events like the one provided by the railways. Such charts or tables are time functional, hence dynamic. The assumption here is that astrology that is expected to explain or narrate the past, present or future in human or human system life is not an in situ tested science. It is used to predict the future based on references to the concerned chart on mere reason and belief and hence needs confirmation based on occurrences in binaries of “yes or no” or ternary or supra-binary logic. The subject being function of time has to be dynamic; hence, the author assigns the name “astrodynamics”. The name *astrodynamics* is meant to open a new window for the study into time ab initio running parallel to the astrological studies presently on. Astrology and *astrodynamics* as the author proposes are not similar. *Astrodynamics* is yet to evolve. Mentioned here as advanced information to interested researchers.

What is a genome? Simple; it is the genetic material of a living thing, containing the complete set of genetic instructions. It means the genetic information of any life is preserved in its genome, and the annotation is the first step to explain the sequence. It is a complete haploid set of chromosomes with its associated genes in every form of life. Usage of the word does not mean it is about those 23 pairs of separate chromosomes (total 46 holding hands like children in a buddy line-up side by side on a museum visit) numbered and tagged more or less in a descending order of size except for the one that deals with the sexual regions of X and Y chromosomes.³ Chromosome 1, in this 23 pairs in humans, has the largest number of genes (2968), and the Y chromosome has the least (231). With the subject of genome, the knowledge world will not only be re-established in the post-information technology era but also enriched by knowledge addition. That is why it is always said a little knowledge is dangerous. But the problem is that it is only a little knowledge the humankind can gain in a hundred or more generations on any topic. So, the individual humans have to carry on with a little knowledge on this and that too very carefully, like a sapper treading a minefield. Therefore, it is the approach and awareness about the little knowledge that the humans possess that is important when it is taken out for implementation. Like drinking the water from the calfskin pouch when trapped in a desert—just nurse it to wet the lips. Not more. There is a difference, though. In the case of a little water, it is depletion and non-availability at critical time, whereas with a little knowledge, it is exceeding the rate beyond which one cannot see. The effect is immediate. There will be knowledge breakdown and pandemonium associated with it if ventured outside the boundaries of one's knowledge system, except for extremely careful research. There is never a situation of knowledge overload. Genomic security belongs to this category of knowledge limitations. This is more dangerous in the hands of the government and other policymakers than in the hands of scientists who know it better as long as they are under control, unless the scientists are under the spell of negative governance. National security Frankensteins are created in government power centres and policy rooms by “a very little knowledge lacing lot of power”—the perfect spark that can detonate an invisible mushroom of inflammable gas into an inferno of disaster. Policy-induced catastrophes in national security management occur in this manner. The paranoia of “conventional” weapons of mass destruction (WMDs)—nuclear, biological and chemical, where biological fears are those related to pandemics and epidemics—still lingers on. More lethal WMDs are in the offing. In creating them, the deadliest of any combination could be the marriage between arrogant power and abject ignorance. It is a proven hypothesis in the biomodels of history. At least genomic security has to be viewed from this perspective when policy decisions are taken lest there should be disasters of assorted kinds—caused by abuse or missing opportunities, the opposite of taking advantage of opportunity.

³The number (23 here) does not hold any significance to relative domination among species. Many species, including apes, have more chromosomes. Many others have fewer.

23.2 Genomic Security: Setting

Genomic security as an element of national security is about governing genomic terrain for human well-being. Genome comprises the building blocks of life in the mysterious genomic terrain. The terrain contains genetics—the study of genes in biology. Genes are the biochemical instructions written inside the cells of every living organism. Genetics is the study and research on how the information encoded in genes is used and controlled by cells and transmitted from one generation to the next. Geneticists also study how tiny variations in genes can disrupt an organism's development or cause disease. Genetic engineering is the study of engineering the genes for purposes of advancement in life forms. It also has the potential for serious abuse, concern of which has presented society with many ethical and legal controversies. Hence, the term “genomic security” can cause havoc if goes out of hand. Genomic security deals with the branch of genetics and its future and possible impact on national security. It is an element that is very futuristic and in an exclusive terrain of its own—the genetic world moulded by deoxyribonucleic acid (DNA), the building block of life. Genetic information is encoded and transmitted from generation to generation in DNA, a coiled molecule organised within chromosomes that lie in the cells. Segments along the length of a DNA molecule form genes. Genes direct the synthesis of proteins that carry out all life-supporting activities in the cell. Although each life form shares the same set of genes, individual life forms can inherit different forms of a given gene, making each one genetically unique.

A genome is the complete set of genes that makes a particular life form. The pairs of chromosomes are numbered from the largest to the smallest in a descending order. The genes carry signatures of life. They lie in the chromosomes within the cell. The study of genomic security deals more with chromosomes as numbered than genes. Scientists have their favourite chromosomes depending on their studies. It is like running over a newly located beach in an exotic island. But all said and done, the genome is the autobiography of the species that it belongs to, recorded perfectly.

The threat associated with genomic security is unethical and unlawful manipulation of genes using gene therapy, and gene researches going haywire resulting in serious problems to life systems. The site for the genes is the cell. They labour inside it. Some organisms are made up of single cell. Others are made of many kinds of cells, each having a different function. The function of a cell within an organism is determined by the genetic information encoded in DNA. In animals, plants and other eukaryotes (organisms whose cells contain a nucleus), DNA resides within membrane-bound structures in the cell. These structures include the nucleus, the energy-producing mitochondria and, in plants, the chloroplasts (structures where photosynthesis takes place). In prokaryotes, one-celled organisms (unicellular) and bacteria that lack internal membrane-bound structures, DNA floats freely within the cell body. Perhaps it feels good that way.

23.3 Genome

The life on earth is made of cells—some unicellular and others multicellular. They are the basic functional units of a living system. The human body has about a hundred trillion of them. They are less than a tenth of a millimetre across—that small. But there is a world within each one of them. The instructions to manage this world are written in DNA (deoxyribonucleic acid), a molecule inside the nucleus of the cell. The molecule is composed of two polynucleotide chains that coil around each other to form a double helix carrying genetic instructions for the development, functioning, growth and reproduction of all known organisms and many viruses.⁴ DNA and ribonucleic acid are nucleic acids. The functions of nucleic acids have to do with the storage and expression of genetic information. DNA encodes the information the cell needs to make proteins.

The nucleus of a cell carries two sets of genomes that contain the complete set of DNA.⁵ As mentioned, DNA contains all the instructions needed to direct the activities of a cell when it is alive. Out of the two sets, one is from the father and the other from the mother, no one else,⁶ wow! These sets contain thousands of genes (about 60,000–80,000—not sure yet) in each. Each of these sets is within a carrier called chromosome that lies inside the nucleus. In fact a chromosome is actually a composite form of DNA. There are 23 pairs of chromosomes in a human genome, which is the complete set of human genes.⁷ Phew, a human is made!

To reiterate a rather complicated subject to the uninitiated, including the author, who has neither the intention nor the capability to rearrange an unsuspecting and home-loving DNA of a human into that of a werewolf or a pet dino, a genome is, thus, an organism's "complete set of DNA". Got it? If not, read again; this time loud. The time has come for the world to know about genome and its unusual affairs, away from the probing eyes of sensationalists that have been so far limited to select textbooks or the world of exotic biolabs. So, what is a genome? It is all the hereditary information which means all the genes of an organism.

⁴A virus is non-cellular and replicates only inside a living cell of an organism.

⁵Except in a sperm and an egg cell that carries only one set. Matured red blood cell has no genome.

⁶Additionally, genes can exist in slightly different forms, called alleles, which further contributes to genetic variation. An allele is a variant form of a given gene. It is one of two or more versions of a known mutation found at the same place (genetic locus) on a chromosome.

⁷Ridley, M. (2000). *Genome: The Autobiography of a Species in 23 Chapters*. HarperCollins Publishers India. p. 3. If each pair is taken into account as 1 chromosome, then there are 24 chromosomes because X and Y are counted separately and not as a pair.

23.3.1 *Gene and Genome*

A typical gene contains a few thousand nucleotides, the fundamental units of DNA. The DNA has the same chemical and physical compositions in all organisms. The sequences of the arrangement of DNA decide the type of organism with its own traits. They can be visualised as some kind of identical toy parts. (There are toys that come in many parts with free engaging geometry that the kids can arrange to make a tractor to a battleship to a skyscraper). But in real-life geometry, the parts are not too many. In living organisms, DNA is written by arranging just four words called the bases. The scientists call them A (adenine), C (cytosine), G (guanine) and T (thymine).⁸ It is simpler than assembling a toy crane that may contain too many parts. The number of bases is even less than the number of piece types in a chess game.⁹ Well, it is more mystical than anything it makes.

While the bases of DNA are just four, explaining and appreciating the arrangement may be very complicated. To recapitulate the array of genomic conversation about the humans (the subject of national security deals with humans; hence, this book is centred on them), one can break it into a nursery (style) rhyme for the uninitiated big kids who read this for academic purpose (there is no other specific reason for introducing a non-rhyming rhyme here). Look at it this way¹⁰:

*“About a 100 trillion cells, amen,
 Maketh a body human,
 Take or leave a few,
 And stir a whimsy stew.
 The cells die replicating,
 While the age add on complicating,
 Cells are less, when death comes old,
 Lucky are those who live that old.
 Oh, ho, ho... (Chorus in the background like a belly grind after a heavy meal)
 The cell that contains a nucleus,
 Carries a pair of chromosomes,
 23 pairs in human to be precise,
 (Read endnotes 2 to 4 to concise).
 All numbered in size descending,
 Except the last, though not condescending.
 23 carries a X in female,
 While holding a Y in male,
 When they join together,*

⁸They are nucleotide bases.

⁹Originated from Indian *chaturanga* in the seventeenth century. The game is played with 16 numbers of 6 piece types: *raja* (king), *mantri* or *senapati* (early form of queen), 2 *ratha* (rook), 2 *gaja* (bishop), 2 *ashva* (knight) and 8 *bhata* (pawn).

¹⁰This is a kiddo song wrote by the author out of sheer boredom. The reader can skip it.

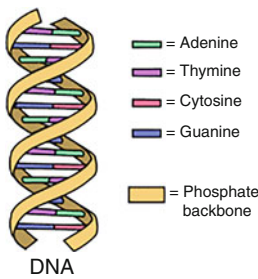

*The life is set for humans to gather,
 Mom gives one and dad another,
 None from a frailty tick-a-dick stranger.
 Whether they wed,
 Or dive into bed,
 Egg and spermo,
 Make it a pretty chromo.
 Oh, ho, ho... (Same exasperatingly discordant chorus in the background)
 The chromos(omes) carry a complete set,
 Of genes, those carry generation next.
 Genes in the chromo power the throttle
 Of life, like a genie in the bottle.
 Genes are not in tens or scores,
 In thousands you can clearly address.
 Each of the gene is built by exons,
 Left in sets that broke by introns,
 Strong they are that made of codons,
 Written in bases, even for morons.
 Four bases tally for all,
 Aye, Cee, Gee, Tee, ready on call.
 That makes the genome for all,
 With billion bases to count in all.
 Oh, ho, ho... (Chorus...)
 A symphony of life,
 They jointly vie,
 In tune with rhapsody
 In perfect medley.
 And, to make it all in a tray,
 Ye know it all; the scientists have their way.
 If they slip a notch on fine,
 Ye, be sure to meet, the Fran-ken-stein."
 Oh, ho, ho... Oh, ho, ho... (Dissolves away, in Doppler...)*

Got it? No? Doesn't matter; all in the genes. Meanwhile have a peep into the Box 23.1 and a look at Fig. 23.1.

Box 23.1: Love You Chromosome

Chromosome is a long DNA molecule with part or all of the genetic materials of the life form. Humans have 23 pairs of chromosomes in their cell. Twenty-two of them are body chromosomes called autosomes; one pair is called sex chromosomes called allosomes. They determine male or female: Y chromosome for male and X chromosome for female. Shape and size of each chromosome vary. Each chromosome has a specific set of genes that is same from person to person. One copy of each chromosome in a pair is inherited from each parent. Each chromosome has three parts: centre with two arms like

(continued)

Every living thing has DNA carrying heredity information that instructs the cells to produce protein. Proteins drive the body functions. DNA decides everything about the being—about life and death... It is arranged in a double helix strand. Each strand of DNA is made of four types of molecules also called bases: A, C, G and T. They pair in a specific way: A with T and C with G. The best way to call them is ATCG because of this pairing. DNA is packed in chromosomes (box). DNA determines the traits. Life is DNA.

Fig. 23.1 About DNA on the run. (The diagram of DNA is from Wikcommons in “Building Blocks of the Genetic Code.” <https://www.ashg.org/discover-genetics/building-blocks/> where DNA is considered the body’s instruction manual.)

Box 23.1 (continued)

extensions from it one either side. The centre is called centromere and the extensions telomeres. Telomeres are caps that protect the chromosomes. But they get eroded as age catch up and fail in protecting the chromosomes invoking the end of the entity; and life continues further through DNA.

Every living thing has DNA carrying heredity information that instructs the cells to produce protein. Proteins drive the body functions. DNA decides everything about the being—about life and death. It is arranged in a double helix strand. Each strand of DNA is made of four types of molecules also called bases: A, C, G and T. They pair in a specific way: A with T and C with G. The best way to call them is ATCG because of this pairing. DNA is packed in chromosomes (Box 23.2). DNA determines the traits. Life is DNA.

In the reverse order, it is simple as projection in rear-view mirror, with the special caveat: not as close as one observes.

- The non-cellular (acellular) biologic form comprising protein and an RNA or DNA genome without a cell structure and independent metabolic ability—virus, virions, viroids.
- The gene: a sequence of nucleotides in DNA or RNA (Box 23.2) is inside a chromosome that is inside the nucleus of a cell which obviously is inside the nucleus; trillions of which makes a human body, and a single cell makes a unicellular life forms, the oldest.
- Unicellular life forms may exist together or alone.
- Lesser than the unicellular organisms is the popularly known virus in the rear-view mirror analogy. A virus is non-cellular. The virus carries genetic material but not alive (well, not dead also according to the author. Zombies... anyone?). Virus is a kind of celebrity zombie of the non-cellular world. They do not grow in size; they do not take in energy; they depend on the host cell to reproduce.

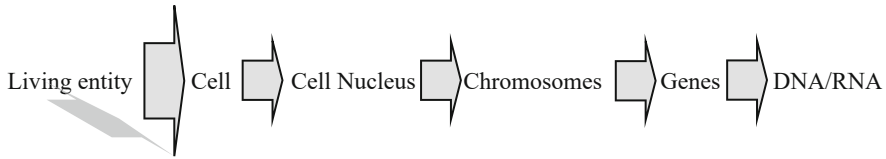

Fig. 23.2 Living entity and DNA/RNA

- There are quite a few celebrities in the unicellular world: bacteria, protozoa, fungi (yeast), algae, archaea, etc.
- Seniors to unicellular organisms are the multicellular organisms such as protists, diatoms, prokaryotes, eukaryotes, etc.

Box 23.2: DNA and RNA: Similar But Different

DNA and RNA are both molecules of life. They are quite close as friends and colleagues, but differently employed.

They are similar as molecules, with same structures with nucleotides, but functionally different. DNA is a kind of repository that stores the genetic code. It is a big vault. It stays in the nucleus of the cells of eukaryotes.¹¹ RNA performs various functions that include that of postman carrying information from DNA to various parts of the cells where it is used to make proteins. RNA lives in the cytoplasm of the cell. It travels a lot around the cell without accepting any delivery charge—good fellow. Though they function differently, they both follow the same basic structure. Sorry, they are not when one looks at them closer.

DNA is double stranded; RNA is single. Poor fellow. But it has no complaints. DNA is long; the entire chromosome is a single molecule of DNA. RNA is quite short. DNA is longer in name too—deoxyribose—whereas RNA is only ribose, less spelling, but has an extra hydroxyl group (OH⁻) which DNA doesn't have.

DNA and RNA also have nearly identical nitrogenous bases. The bases A (adenine), C (cytosine) and G (guanine) are common for both. The fourth bases are different. DNA has T (**thymine**), and RNA has **uracil**. The only difference is that uracil doesn't have CH₃ (**methyl** group). No, it doesn't look like a kid with one front tooth missing.

Figure 23.2 shows the relationship of a living entity figuratively with its DNA/RNA

¹¹Eukaryotes are organisms (protists, fungi, plants, animals, etc.) whose cells have a nucleus enclosed within membranes; opposite are prokaryotes (bacteria and archaea), which have no membrane-bound organelles.

It is said that there are 37.2 cells in a human body. Of course, anybody is free to count and disprove this statement) (Box 23.3).

Box 23.3: Cell and Non-Cell of Life

Life at the apex divides into cellular and non-cellular. But the idea of the non-cellular virus as a living form is not quite acceptable. It is also not dead. That makes it complicated for a layperson to understand. The cell and non-cell argument of life therefore is a bit mired. But it doesn't have to be. Viruses are non-cellular also called acellular, meaning they are biological entities that do not have a cellular structure. They therefore lack most of the components of cells, such as organelles, ribosomes and the plasma membrane. Viruses are sometimes called virions: a virion is a "complete" virus free in the environment (not in a host). They are more like androids. Some consider virus as a life form because they carry genetic material, reproduce and evolve through natural selection. But where the cellular structure is the criteria for life, the non-cellular virus loses the chance. For this study, virus is non-cellular, and a human is cellular life form. Life and death doesn't come in between as they cannot be compared as prominently as cell and non-cell.

23.4 Coming to Sapiens: Human Genome Project

The awareness of the world about genomics can be traced back to human genome project (HGP) that was widely publicised in the last decade of the twentieth century. But only a few are aware that this was not something new. Human interest in genetics had a long past. The human genome project has its roots in an initiative of the Department of Energy of the US Government as far back as 1947.¹² It was when the Department of Energy was tasked to develop new energy resources and technologies. In 1986, the Department of Energy announced the Human Genome Initiative (GNI). It was followed by the announcement of HGP. Officially, the project began in 1990. Subsequently, international cooperation rolled in.

The DNA was there in the beginning; otherwise, there wouldn't have been life on earth. Crudely, it was also thought about. Erasmus Darwin (1731–1802), a poet cum polymath and the grandfather of Charles Darwin who revolutionised the theory of the origin of life 60 years later (was it in the genes?) had thought about the living filaments of life as the cause of all organic life on earth quite loudly in 1794.¹³ It might have been a startling guess at that time. But certainly the guess of the intuitive is more constructive than that of the speculative gambler. The idea of something like

¹²US Department of Energy. "The Human Genomes Project". 1990–2003: A Brief Overview, www.ornl.gov, 20 January 2004.

¹³Ridley, M. (2000). *Genome: the autobiography of a species in 23 chapters*. HarperCollins Publishers India. p.12.

this does not rest with Erasmus Darwin alone. Even Aristotle is attributed with the idea of the recipe of life for identifying it as a technique for replicating and creating order. Aristotle said that the concept of chicken is implicit in an egg. It is the “information theory” of Aristotle that has resurfaced in the discovery of DNA years later.¹⁴ The discovery of DNA structure was made by James Watson and Francis Crick (1916–2004) in 1953 that heralded the era of molecular biology. Watson and Crick came to be known as the discoverers of the double helix.

The filament of the DNA is information written in a chemical with one chemical for each letter in a code. It is written in a linear language that can be read. This was the basic purpose of the genome project—to generate a reference DNA sequence for the 3 billion base pairs and to identify all human genes. There were other goals too. In June 2000, the first working draft of the entire human genome was ready. The high-quality reference sequence was completed by 2003. The HGP will pave ways for a number of researches that will yield high-quality disease combating medicines and methods. It will have indefinite practical applications including identifying genes associated with human diseases. Hundreds of other genome projects on other organisms—plants, microbes, animals, etc.—will follow. The genome projects are not just sequencing alone. There is a lot to know since the genome entry is only the beginning. But there is bioethics community keepers¹⁵ who have a stake in it or the society as the stakeholder may wield bioethics as the final arbiter in controlling genetic chain reactions. The governments have to be on both sides.

Current knowledge is limited to recent experiments on the subject and is changing. There are surprises too. Anybody will agree that humans look different from fruit flies (of course, a fruit may not know). But the humans are very modest relatively with the simple fruit flies in the number of genes as if it is more economical to assemble a human than a fruit fly from all points. While a human have about 30,000 genes, a fruit fly is not very distant; it has around 13,000. Table 23.1 compares the genes of select life forms

Further studies showed that the humans have about 20,000–25,000 genes. That was close to *C. elegans*, the roundworm and less than that of a small flowering tree of the mustard family which has 27,000 genes. The number is not what actually determines the complexity of a system, but the way the genes are used by nature to run the system.¹⁶

The number of human genes, as understood today, is much lower than what was previously thought. The scientists believe that number is not the criteria compared to the process used for building different products. The process is called alternative splicing. Another complexity in understanding the building process of human

¹⁴Ibid.

¹⁵ELSI in summary from Wikipedia, the free encyclopaedia. The acronyms ELSI (in the United States) and ELSA (in Europe) refer to research activities that anticipate and address ethical, legal and social implications (ELSI) or aspects (ELSA) of emerging sciences, notably genomics and nanotechnology.

¹⁶“How Many Genes Make a Man?” *Hindustan Times*, New Delhi. 22 October 2004. p. 23.

Table 23.1 Genes: Select organisms^a

Organism	Genre	Genome size (number of bases)	Genes (estimated)
Human	<i>Homo sapiens</i>	3 billion	30,000
Laboratory mouse	<i>(M. musculus)</i>	2.6 billion	30,000
Mustard weed	<i>(A. thaliana)</i>	100 million	25,000
Roundworm	<i>C. elegans</i>	97 million	19,000
Fruit fly	<i>D. melanogaster</i>	137 million	13,000
Yeast	<i>S. cerevisiae</i>	12.1 million	6000
Bacterium	<i>E. coli</i>	4.6 million	3200
Human immunodeficiency (retro)virus ^b	HIV	9700	9
Covid-19 (retro)virus ^c	SARS-CoV-2 Coronavirus family	29,903 is around bp ss-RNA	Ongoing research (2020)

^aPaleri, P. (2008). *National security: imperatives and challenges*. Tata McGraw-Hill Publishing Company Limited. p. 373

^bA retrovirus carries single strand RNA as its genetic material unlike the double-stranded that the cellular life forms carry. Retroviruses also have the enzyme reverse transcriptase, which allows it to copy RNA into DNA and use that DNA “copy” to infect human, or host, cells

^cStudy identifies new “hidden” gene in Covid-19 virus. Overlapping gene in SARS-CoV-2 may have affected its biology and ability to spread. <https://www.sciencedaily.com/releases/2020/11/201110133141.htm>. Accessed 28 February 2021. Presently the studies are on (2021)

genome is in the protein modifications and their regulatory mechanisms. Proteins perform most life functions and even make up majority cell structures. They are complex molecules made up of amino acids, the smaller subunits of protein. The constellation of all proteins in a cell is called a proteome. It is dynamic and changes to the demands of the external and internal signals of the environment dynamically to respond favourably as decided by the relatively unchanging genome. The gene sequence decides the behaviour and chemistry of the protein.¹⁷ About 2% of the genome encodes instructions for the synthesis of proteins.

The human genome is an ocean of information. The discovery of genes is only the beginning of the voyage through it. Only the surface is skimmed so far. The sizes of genes vary. The largest is dystrophin with 2.4 million bases. Functions of more than 50% of discovered genes are yet to be identified. It has been discovered that the sequencing is exactly identical to almost 100% in all the people. The research in genome is expected to provide high yield in the twenty-first century, especially in the field of health sciences. These include molecular medicine, microbial genomics and health risk assessment; anthropology and human migration; DNA identification in forensic medicine and criminology; agriculture; livestock breeding and bioprocessing towards maximising food security; etc. The dimensions of genome

¹⁷US Department of Energy. “The Human Genomes Project”. 1990–2003: A Brief Overview, www.ornl.gov. Accessed 20 January 2004.

Table 23.2 Genetic comparison: Similarities (percentage)

	Organism	Percentage
Human	Human	99.9
Human	Chimpanzee	96/98.7

Human	Yeast	26
Human	Plant	18

research are expansive. And so are the criminal and anti-national security aspects, if the countries are not careful. Bioterrorism and biological warfare can take an entirely new turn when genetics turn around in wrong hands.

Human beings are similar to other humans and very close to other living things in their genetic design. The difference between one human with another is less than 0.1% in a casual assessment.¹⁸ The claim is that people are 99.9% genetically similar. This difference is very negligible relatively considering the creative forces, but infinitesimally large for a human just enough to make him or her not at all similar to the other person. This brings out the most mystical aspect of at least the sapiens: “there was never ever one like him or her and there will never be”. That is the “point one magic”.¹⁹

Human beings are expected to have around 3 billion base pairs.²⁰ Among them only the “point one pairs (0.1)” are unique to each individual. Otherwise everyone is similar to the next human. This perhaps can explain the “singularity” and “differentiality” in the personalities of sapiens mentioned earlier, though it has a lot to do with human conditioning subsequently in life. Everyone is conditioned differently on a singularity base in behavioural aspects. Table 23.2 gives another comparative study on similarities.

Sharing of genes with other living things gives the hint on evolutionary process and what it means to be a human being. The amount of difference in DNA in the

¹⁸ Pflanzner, L.R. and Lee, S. “Our DNA is 99.9% the same as the person next to us—and we’re surprisingly similar to a lot of other living things”. <https://www.businessinsider.com/comparing-genetic-similarity-between-humans-and-other-things-2016-5?IR=T>. Accessed 12 January 2019.

¹⁹ Author’s find. 0.1 magic is the difference that separates one human from another, and it is expected to apply to other life forms also. The difference should reduce as it goes down in the cellular reduction finally becoming equal with each other as unicellular. Or does it?

²⁰ The DNA molecule comprises two strands that wind around each other like a twisted ladder. The rung of the twisted ladder is formed by the base pair which is two chemical bases bonded to one another. Attached to each sugar is one of four bases (nucleotides)—adenine (A), cytosine (C), guanine (G) or thymine (T). Thymine is replaced by uracil (U) in RNA. But the bases bond as A-T, C-G

genome is a test of the difference between one species and another. It can give a picture of how close and distant they are in evolution.

23.5 Universal Genetic Code

Every living organism has genes that are made of DNA which is considered a universal genetic code that makes every life form typically similar from an entirely different life force perspective—the force that made or controls the continuum process of life in metastasis of reality and abstraction that is not unreal. This statement apart, it concludes that every known living form has genes made of DNA. They use the same system.

The genetic information of an organism is stored in its DNA. This includes some viruses. There are also exceptions of some viruses. The complete set of DNA of an organism is its genome. The DNA uses the four bases—A, C, G and T (Aye, Cee, Gee, Tee...Oh, ho...ho... for the layman like the author. Remember?). The RNA uses the base uracil (U) in place of T (thymine). All organisms make the same amino acids. This knowledge makes the whole process of life's mystery relatively simple to understand and how different species are related. This information comes from what the scientists call, the universal genetic code. It is the DNA because every known life form, from bacteria to humans, has genes made of DNA. The DNA stores genetic information.

Life is one big singularity reflected in the universal genetic code (UGC). The DNA, therefore, is an ancient text of sorts showing ancestral contributions to all living forms within this singularity. The DNA also transcribes RNA and translates that RNA into proteins, the essential nutrient. In other words, DNA provides the code for the cell's activities, while RNA converts that code into proteins to carry out cellular functions.

DNA mutates and species transform. Mutations occur at relatively steady rates. This can be examined in two different species and assessed through what scientists call molecular clocks to estimate the span between them. The span will tell how long ago the two species shared one ancestor. For example there is only one nucleotide difference between humans and gorillas. It means one mutation. That means human may hug them but don't eat them. Chicken is fine. There are 45 nucleotide differences. The span is too long to forget brotherhood—45 mutations.²¹

The DNA of every organism does the same job: transcribes RNA that translates into proteins. The evidence of evolution of life lies in DNA and the system DNA to RNA to protein for life. That is why DNA is considered the universal genetic code. Cells come from parent cells inheriting the parental DNA. Heredity is created by such inheritance.

²¹Slizewska, G. Universal Genetic Code (Evolution)—Evidence & Examples <https://www.exprii.com/t/universal-genetic-code-evolution-evidence-examples-10260>. Accessed 20 September 2019.

23.6 Genetics and Human Health

The organic aspect of human health is associated with DNA sequencing. If that is so, then the secret pathways towards human health lie within DNA. Its impact will be on diagnosing and treatment of diseases. This fact, therefore, will be vital for genomic security because of competition and regulatory measures violation. The transformative methods associated with health include many processes. Gene testing, pharmacogenetics²² and gene therapy are developing fields.

23.6.1 *Gene Testing*

Gene testing has various uses. Diagnostics, prognosis, confirmation and prediction are primary uses. Gene testing can help in diagnosing a disease, provide prognostic information about the course of a disease, confirm the diseases in non-symptomatic conditions and also predict its likely chances in a human being in the future. Gene testing is expected to replace most other tests now carried out in health assessment. Large number of tests is already undertaken in clinical medicine, and more are expected to include. Rigorous experiments are going on in gene testing all over the world. These tests are not foolproof since they also have scientific limitations. Another aspect is the ethics of predicting a disease since it can have significant emotional and psychological impact. There are chances of identifying a particular group of people to be high risk and thereby causing a stigma on the group. It will cause serious problems in other fields of national security related to ethnic and demographic security.

Introducing gene testing in clinical practice needs regulatory measures and legislation. This may include laboratory quality assurance, ethical practices, capabilities of the medical unit to carry out gene testing, etc. The subject will also open up avenues for many medical practitioners with specialist qualifications. Its impact will also be seen in educational fields related to the subject matter. Counsellors are other people who need to be trained on the subject because gene testing can also cause emotional problems as mentioned before.

²²Pharmacogenetics is the study of how people respond differently to drug therapy based upon their genetic makeup or genes. Diet, overall health and environment also have significant influence on medication response, but none are stronger indicators of how you will process medication than your genetics.

23.6.2 *Pharmacogenomics*

Pharmacogenomics will deal with customising treatment for a particular group of people. That will be a major shift from today's singular medicine therapy for all. Custom medicines are on the way for groups if not for individuals. Pharmacogenomics mixes pharmacology with genomics. One of the advantages of custom medicine is to avoid the dangers associated with today's medication. Large number of deaths in the world is attributed to wrong medication and larger numbers suffer from serious reactions. There are also patients who may not react to a medicine at all. Pharmacogenomics will observe these points and study more on drug metabolisms. The patient's genotype will hold the key for application of medicines. It is expected to drastically reduce adverse effects of medicine.

Drug development will undergo major change through pharmacogenomics. Faster, cheaper and more effective drugs will be the result. Genomic research will deal with the disease-specific genes, pathways and drug-response sites dealing with many molecular targets that today's drug research is not capable. Such medicines may have fewer side effects when biochemical events leading to diseases are known through genomic signatures of individual humans.

23.6.3 *Gene Therapy*

Gene therapy is the better-known aspect of genomic applicability in health. Genes lie deep within cells, the building blocks of all living things, well arranged as small sections of the DNA inside the chromosomes. Genes carry genetic information and instructions for making proteins, which help build and maintain the body. Using these genes therapeutically for health is gene therapy. It is a hot subject. Here genes are the therapists. Gene therapy is also known as transfer. A section of biomedical geneticists believe the cure for treatment for terminal diseases like cancer and AIDS lie in gene therapy. Gene therapy largely includes replacing defective genes with healthy ones. Safety and effectiveness are the key issues.²³ Cell and gene therapy are fun.

Gene therapy may have serious takers in the world of sports and athletics. One of the hottest topics today is improving the performance of an athlete by gene therapy. Genetically modified (GM) opponents may become a threat to other naturally born and living athletes because the doping may not be easily identifiable. They will get the competitive edge. And what happens when every athlete gets modified genetically? One will try to outsmart another. Where will it end? Gene transfer faces many issues in its implementation. Gene therapy is still in its experimental form of treatment. The scientists try to cure disease by replacing malfunctioning genes with healthy ones. Gene therapy has shown promise in treating some devastating

²³Ibid.

conditions, including some forms of cancer and cystic fibrosis. Genetically engineered vaccines are being tested for possible use against the human immunodeficiency virus (HIV), the virus that causes AIDS.

Gene therapy, undoubtedly, represents huge medical breakthrough in the future. Its therapeutic implications are huge and range from being used as the first effective treatment for wasting diseases, such as muscular dystrophy, to preventing vulnerable growth problems in vulnerable children. But the same approach can also be adopted to manipulate muscle development so that power, speed and endurance can be enhanced in sport. It can be very appealing for sports persons. Gene therapy can alter the proportion of fast and slow twitch muscle fibres to aid sprinters or marathon runners, respectively. An injectable synthetic gene can block myostatin, a substance that limits muscle growth, which could benefit power and strength athletes; gene to produce synthetic EPO (epoetin alfa) and, thereby, boost the body's oxygen-carrying capacity are also being investigated. And so far there are no confirmed side effects, though the studies carried out are limited.²⁴ It is only a matter of time someone sets up a lab offering performance enhancing gene therapy. That is how experts resign to the fact about gene therapy that has gained acclaim through stem cell research (Box 23.4).

Box 23.4: What Is the Connection Between Cell Therapy with Gene Therapy?

Cell therapy is associated with gene therapy. Cell therapy overlaps with gene therapy in medical research and treatments today. Both are used to treat the underlying cause of genetic disease and acquired diseases. But they work differently.

In cell therapy, the cells are cultivated or repaired external to the body and then transferred into the body to treat diseases. In some cases, cells carry the therapy as a therapist. These cells can be autologous (own) or allogeneic (donor). Gene therapy uses genes as therapists by inactivating, introducing or replacing genes into cells, externally (*ex vivo*) or internally (*in vivo*). There are also therapies that are combinations of cell and gene therapy. The bottom line is maintaining the building blocks of life—the cells.

23.6.4 Stem Cell Research

Stem cells are versatile cells that have the ability to grow into any kind of tissue. The cells can be procured from adult patients own body (from bone marrow, blood, etc.) or from embryos—more potent than adult stem cells—or from umbilical cord blood.

²⁴Bee, P. "Sport Braced as the Gene Genie Escapes from Its Bottle". *Hindustan Times*, New Delhi. 14 September 2004. p. 1. (Though this athletics based article is quite old the situation, 15 year later is not of much different.)

They are injected into the body directly intravenously, endocardially or straight into the heart. Stem cells repair the damaged cells of the body. The types of stem cells are:

- *Totipotent*. They can turn into any type of a cell in the body, including placenta.
- *Pluripotent*. They can turn into any type of a cell except placenta.
- *Multipotent*. They can turn into only some types of cells, hence, of limited use.

Stem cells can treat muscular dystrophy, a group of genetic disorders that cause progressive wasting of the muscles. The idea needs to be seen ethically for testing on patients. The finding in the research confirms that human donor cells can be successfully incorporated into a recipient's fibres.²⁵ This has raised hope that patients with all kinds of degenerative diseases could be treated with stem cells from their own marrow. Because, according to research, the blood forming stem cells of the marrow can turn into the cells of other tissues like brain and heart. Cells from lips are removed and used to correct a damaged eye through stem cell therapy. Human embryonic stem cell research can lead to biological pacemakers that can treat heart attacks with regenerated tissues. In another investigation, researchers stated that blood-forming stem cells of the marrow make only blood. Marrow contains other types of stem cells besides blood-forming stem cells like stromal or mesenchymal stem cells. There are also reports that improved heart functions are seen in patients treated with their own marrow stem cells.²⁶

Stem cell research provides hope for millions of paraplegics in the world finding a way to rebuild the nervous system. Embryonic stem cells are master cells that have the potential to develop into virtually every type of cell in the body. Scientists take the genetic material from a cell and fuse it with an empty egg cell which is then biochemically persuaded to develop into an embryo. Cloning plays an important part in this process for the simple reason that it allows creation of perfect match tissue. But cloning for stem cell research is banned in certain countries. It is therapeutic cloning and not strictly embryonic cloning as many critics think. And, if it is controversial, it is because it involves many medical, ethical and legal issues. Pro-cloning researchers have declared that they would go ahead with cloning irrespective of opposition.²⁷ According to experts, cloning is a subject that is not yet mastered properly. Therefore, results could be unpredictable. The anti-cloning constituency points out medical dangers and ethical and moral dimensions of playing with human life. But it is business, and the target in 2001 was 70 million infertile people. And the number is increasing. Criticism is that scientists create something that has life and discard it after utilising its parts, after harvesting some cells. "Then what about the embryos thrown away deliberately in fertility clinics?" is

²⁵Wade, N. "Stem Cells Opens New Vistas". *The Asian Age*, New Delhi. 19 September 2002. p. 17.

²⁶Ibid.

²⁷Rajghatta, C. "Human Clones within a Year: Researchers". *The Times of India*, New Delhi. 9 August 2001. p. 1.

a question the advocates of stem cell research ask. “There are many such critics but for whom the research would have been much advanced”, state the supporters.²⁸

Stem cell research has already met controversies with the politicians in the fray for winning at the vote banks. Their engagement with scientific establishments in today’s knowledge world can be much revealing with their own priorities and topics of discussion. Stem cell research is one of the areas where differences can be found. In 2001, George W. Bush, then US president, froze funds for embryonic stem cell research questioning its ethicality, whereas many life scientists are of the view that such research is essential for the health of the world population in the future. According to Bush, he had no plans to stop stem cell research as long as it was within the moral lien.²⁹ John Kerry, his political opponent in presidential election, stated a little more to edge out Bush. He wanted to go beyond the ideologically driven limits by overturning the ban on federal funding on new stem cell research. The political bandwagon rolls in genomic security in its normal fashion as in other cases. One cannot segregate the political institutions in any kind of research or topics in national security. Politics is embedded in it more than human well-being, the national security itself, if one can say.

It is interesting that, today, in the genome scenario, a human being could offer oneself as a spare part store. The concept of body shop may change into genome shops with live organs for sale. Kidney, liver, heart and anything that can find a market could be piped to the customer, many of them rich. Blood and eye donation are regular legally accepted body sales. There are many men and women in the age group of 20–40 selling their fertility to those who are infertile at a generous price.³⁰ These sales may not be legal but certainly rationalised by the people involved in it. The question is not just ethics, but reversing the balance of nature in population control. It is a serious matter. The impact of such fertility explosion is not studied. But certainly there is something that can be seen as a hypothesis that population is a controlled propagation by nature. There are easy to see evidences in nature itself.

It is possible to prepare eggs grown from tissues of aborted foetus, according to researchers.³¹ The study would help to solve worldwide shortage of donor eggs for fertility treatment and medical research. The research raises lot of ethical questions. Therefore, it is not to go on licence in the foreseeable future. In China, it is reported that cells from aborted foetuses are used for treating certain diseases. The cells are injected into the brains and spines of the sick and disabled. This is one of the controversial treatments in the sphere of genomic activities. The practitioners claim to have treated people with spinal disability like amyotrophic lateral sclerosis (ALS). The world gets information about treatments through cyberspace.

²⁸“Editorial, Superman’s Sadness”. *The Hindustan Times*, New Delhi. 19 September 2002”. p. 10.

²⁹Jha, A. “Bush, Kerry Differ on Stem Cell Research”. *The Hindu*, Coimbatore. 17 September 2004. p.14

³⁰Gupta, S. “Mumbai Girls Sell Eggs for Rs. 20,000”. *The Asian Age*, New Delhi). 11 June 2004. p. 1.

³¹“A Baby from an Unborn Mother is Possible”. *The Asian Age*, New Delhi). 2 July 2003. p. 1.

Paraplegics and ALS sufferers are converging for treatment to China according to reports; however, the treatment has not been proven by western scientific standards. According to report, for better results, the embryos should be at least 16 weeks old and the mothers give away the embryos willingly and not receive any payment for that. Research on cell implants goes back more than two decades. The results in Western laboratories show positive benefits of stem cell research on neurological disorders. But opinions vary. According to Chinese practitioners, stem cell transplants on humans are with poor results. The Chinese treat with foetal olfactory ensheathing cells on humans.³²

Researchers from Cardiff University's Wales College of Medicine have succeeded in devising a way to make human eggs behave as if they have been fertilised without using sperms. The team believes that this could provide a more ethically acceptable way of creating "embryonic" stem cells. According to findings, researchers used an enzyme found in sperms prompt the egg to divide. They felt the enzyme could also be used to help childless couples because the male sperm has very little of this key protein called phospholipase C-zeta (PLC-zeta) that plays a key role in activating the egg, allowing it to be fertilised. The team found the embryo appeared to undergo the same changes as naturally fertilised eggs, suggesting they would also be able to produce stem cells.³³

Experts in India in stem cell research are confident about the results and the way it is going to change the future. Indian doctors have tried stem cells in cardiac treatment. The All India Institute of Medical Sciences (AIIMS) at New Delhi, India, is a unique institution. Its uniqueness does not come from its noteworthy contributions to medical sciences in research and applications alone. Its doctors and other medical practitioners cater from the bottommost to the topmost in social hierarchy with equal ease and demeanour. The patients are attracted towards the institution by sheer competence on one side and as a national institution that caters for the poor without prejudice. The doctors are so immersed in their work that they see a patient as a patient and a challenge to health sciences, which in their hands is to solve. No wonder they have claims that they make modestly which will make one sit-up and think seriously. In India, every kind of disease exists. People are often diagnosed at a very late stage. According to Dr. Venugopal, a cardiologist who heads the Institute, stem cells are useful because of their regenerative aspects. Stem cells extracted from patient's bone marrow or, in the case of a newborn, from the umbilical cord, are simply the building blocks of life. Umbilical cord blood banks offer amazing medical recipes as they freeze stem cell samples at -270°C under cryogenic conditions. According to Dr. Venugopal, these cells can be used 50 years after a person is born to treat ailments that may develop due to genetic predispositions. Stem cells could be crucial in trauma cases that may address comas and brain damages considered irreversible. The simple umbilical cord, cut and thrown away as

³²"World Flocks to China's Stem Cell Doctor". *Hindustan Times*, New Delhi. 2 December 2004. p. 20.

³³"Eggs Fertilised without Sperm". *Hindustan Times*, New Delhi. 4 December 2004. p. 22.

a medical waste, is becoming the lifesaver true to its name. It could revitalise cardiac tissues as the AIIMS doctors have found out by stem cell research. That will be further extendable to kidneys, liver and brain too according to them.³⁴ It is a question of not just health but also of well-being of humans. There are medical professionals for whom it is a great feeling to see a patient walk away leaving the bed empty not by death.

The research in the AIIMS showed that stem cells can treat cardiovascular disorders, diabetes and neurological disorders like stroke, muscular dystrophy, cerebral palsy, liver regeneration, eye injuries, etc. These researches are also under progress in other countries, not in India alone. The AIIMS has planned an umbilical cord stem cell bank. The methods preferred are outside the ethical concerns since the umbilical cord is discarded along with placenta after childbirth. Before discarding, the blood from the umbilical cord will be retrieved and purified for stem cell generation. These cells could be cryopreserved under deep frozen conditions for treatment. More than 43 diseases can be treated by stem cells from the umbilical cord. These include various genetic disorders that affect the blood and the immune system, leukaemia and certain cancers as well as some inherited disorders of body chemistry.³⁵ While in Russia, there are claims of using both adult and embryonic stem cells for all kind of treatment—from wrinkles to Parkinson's disease to impotence.³⁶ Most of the treatments are illegal and scientists warn of quacks who may fleece their clients of their money and health. Enforcement is lax. There are patients in Russia in wheelchair after spending US\$20,000 for stem cell treatment by quacks.³⁷ According to experts, the procedures carried out in Russian clinics are potentially dangerous to human health with dangerous side effects. But a good number of clinics continue operating on the side lanes in Russia.³⁸

Stem cell therapy is limited to a few institutes. Advanced research in stem cell will take some time. The market potential and legislation need to be established since the investment is quite high. Most of the pharmaceutical research organisations are assuming a wait and watch method. In India, the Department of Biotechnology (DBT) is spearheading the procedures along with the Indian Council for Medical Research (ICMR). There are issues like prevention of duplication of efforts and standardisation of techniques that need to be looked into. One of the challenges that face the researchers is identifying the stem cells. Stem cells are found in born

³⁸*Ibid.*

marrow, blood, skin, etc. They have the ability to differentiate into other kind of cells.³⁹

Issue of stem cell research and controversies are not complete without a reference to Hollywood actor Christopher Reeves (1952–2004) widely known for his Superman series. He was a strong proponent of stem cell research. An actor by profession since childhood, he injured his spinal cord in an accident while partaking in an equestrian event in 1995. He was paralysed for life. He proved to be a superman in the most difficult period of his life and motivated researchers and neuroscientists all over the world to conquer such disease till his end on 10 October 2004. He firmly believed in the prospects of stem cell research in curing many of the diseases that takes away effective life from humans and lead them to their end slowly and painfully and helped in bringing awareness, funding and law making. It is for the world to follow such powerful and intuitive suggestions from strong people.

23.7 Genome and Travelling Human

Humans are the most spread out life form. Their evolution has been different from other life forms and has been read backwards through genomic research. According to a study, somewhere in the past about 80 million years ago, there was a tiny shrew like mammal who was considered to be the common ancestor of humans and all other living mammals.⁴⁰ The best estimate of ancestral DNA was a test case through many mock sequences in the computer reconstruction by scientists. Reconstructing the extinct genomes of ancestors of living things has become a part of serious genomic studies. Emigrations can be tracked by train of errors that slowly accumulate in certain regions of DNA. After a population splits, the people who go one way will clock up a different train of errors from those who go the other way. Geneticists can reconstruct family trees of different lineages in the grant genealogy of human-kind and even assign rough dates to the branch points. Y chromosome tracks the movement of men; mitochondrial DNA inherited only from the egg tracks the migration of women. There are 20 mitochondrial lineages. Geneticists use the term drift to explain random change that occurs between generations as some genetic variants become more common and others get rarer or disappear altogether.⁴¹ The drift is what made the people different. But DNA does not hide the drift. Perhaps the only history that is ever written correctly without distortion whatsoever is that in the pages of DNA.

⁴¹Wade, N. "Genetics Helps Decode Early Human Travels". *The Asian Age*, New Delhi. 14 November 2002. p. 17.

23.8 Knowledge Revolution and Genomic Security

Human knowledge in any field theoretically precedes applications, mostly, with extended time gap. This time gap in knowledge appreciation and knowledge application depends upon various factors. The end points of the gap are primed by the intellectual surge in evolution and the application needs. The intellectual evolution generates knowledge. It gets primed into application by survival needs. Till then the knowledge should ideally gets hibernated for intermittent “dusting up” and refurbishing. It is not the same but similar to the tatami mattress. The neatly tucked away tatami mattress in a traditional Japanese family finds its place on the floor in the bedroom normally when the members retire to sleep. The mattress is all the time there neatly tucked away, when not elegantly spread out. But between the periods, the mattress may be dusted or hung in the sun from balconies to refurbish. It may take centuries for the knowledge generated and tucked away in human brain to find application. This is an interesting find in knowledge generation, retention, application and regeneration. But knowledge is not tatami mattress; application period is not controlled by the circadian rhythm. They vary from knowledge to knowledge. This lag is visible in everything in human system including genetics.

Ideation of genetic engineering further developed to genetic technology surfaced in the possibility of manipulation of genetic in 1973. The process of transferring genes from one organism to another was first performed by [Herbert Boyer](#) and [Stanley Cohen](#) in 1973. But the subject originated in 1953 when James Watson and Francis Crick at the Cambridge University determined that the structure of the DNA was a double helix polymer, a spiral consisting of two DNA strands wound around each other. The DNA was discovered already discovered as early as 1869. That’s not all. Gregor Mendel (1822–1884), an Augustinian monk, had already postulated the laws of inheritance and traits in 1869. Mendel is considered the father of modern genetics. That is not all. The entire avatars (incarnations) of Lord Vishnu depicted in *Rigveda*⁴² point to evolutionary genetics that includes the story of genetics and genetic mutations and naturally selective modifications. It only shows people had knowledge at all times as appropriate to the period evolution. They retained refreshed it till applicability needs which for genetics has been nearly 4000 years later, still chugging at the speed of a coal powered locomotive.

The forerunner in genome advancement is the bacterial biotech. The subject has made the highest advances ranging from gene mediated vaccine production to gene-modified pesticides and several other products as well. Genetic advances to make agriculture productivity faced a setback because of the Frankenstein factor in the minds of consumers. Insufficient information in the public domain and secrecy

⁴²Rig Veda is the oldest of the four Vedas. It contains 1028 hymns and 10,600 verses in 10 *mandalas* (books). The verses are recited as it was in the early days in various ceremonies dedicated to various cosmological deities. Rigveda is one of the four sacred canonical texts of Hinduism known as Vedas dated around 1900 BC.

surrounding tests and trials were the major reasons to create suspicion in public mind regarding the side effects of genetically modified agriproducts.

The more contemporary interest after microbial and agricultural biotech concerns the human genome project. Unfortunately, here again, the hype and promises are running well ahead of facts emerging from laboratories around the world, further fuelling the gene bubble. The basic promise is that the information contained in the genes of each one of us represents a template related to health, well-being as well as predisposition to diseases such as cancer, coronary ailments, Alzheimer's, schizophrenia and many other common, and not so common, inherited and acquired ailments. Those involved should not promise more than they can deliver. Then it will stay.⁴³ The knowledge revolution in genomic research supported by IT revolution has been aiming at various functional aspects of genomic security that may support human well-being in the future. The knowledge revolution in genomic security is multifaceted and spread over areas of gene fragmentation, cloning, plant genomics, consumer products, etc. It is poised to spread much beyond the existing realms of gene programmes.

23.8.1 Cancer Prognosis

Genetic makeup could be used in cancer treatment instead of tumour location as practised generally. The Food and Drug Administration (FDA) of the United States has approved a cancer therapy based not on the tumour's primary location (breast, lungs and so on), but on a specific genetic feature found in the cancer's DNA.⁴⁴ The chances of cancer can be weighed in advance preemptively by cancer prognosis techniques.

According to scientific reports, gene samples from tumours can be analysed using microarrays to predict the cancer's treatability. Active genes—long DNA stretches that instruct cells to make proteins—convert their DNAs to matching RNA. In this process⁴⁵:

- An RNA is taken from tumour and chemically treated to be fluorescent.
- Then poured over a DNA chip—a grid of single-stranded DNA fragments representing several thousand genes.

⁴³Ganguly, A. "Till the Genome Bubble Burst". *The Asian Age*, New Delhi. 14 November 2002. p. 13.

⁴⁴"FDA approves first cancer treatment based on genetic makeup, not tumor location". <https://www.cancercenter.com/community/blog/2017/08/fda-approves-first-cancer-treatment-based-on-genetic-makeup-not-tumor-location>. Accessed 10 February 2020.

⁴⁵"From Gene Fragments to Cancer Prognosis". *The Asian Age*, New Delhi. 23 December 2002. p. 6. The discovery of molecules called small RNAs, which control much of genes behaviour, has been named the top scientific discovery of 2002 by the journal *Science*. Small RNAs may further research on cancer and stem cells.

- The RNA binds to its matching DNA.
- If a gene is highly active (many RNA copies per cell), many fluorescent bits of RNA will stick to the chip making that portion of the array fluorescent.
- The chips are scanned with a laser that records the fluorescent intensity of each gene on the chip and produces a visual array.
- A mix of RNA from other tumours with known outcomes and dyed a different colour is also run over the chip.
- Complex pattern recognition software looks at the array of patterns and their colours and then finds genes whose activity predicts either a good prognosis or a poor one.

Cancers begin when one or more genes in a cell mutate abnormally to the expected pattern. Such mutation can create an abnormal protein or prevent normal protein formation. The abnormal protein provides instructions to cells to multiply uncontrollably resulting in cancerous cells. There are two types of genetic mutations: acquired and germline. Acquired mutation is largely the cause of cancer. This happens due to various habits of the person. These are the most common causes of cancer. They occur from damage to genes in a particular cell during a person's life. For example, this could be a breast cell or a colon cell, which then goes on to divide many times and form a tumour, formed as an abnormal at the site. Cancer by acquired mutations is called sporadic cancer. Acquired mutations are not found in every cell in the body, and they are not passed from parent to child. Acquisition can be by tobacco, ultraviolet (UV) radiation (UV), viruses, aging, exposure to carcinogens⁴⁶ in occupational area and so on.

23.8.2 *Cloning*

Cloning is the process of duplicating organisms or copies of cells or DNA fragments in biotechnology and genetic engineering. Such clones will be with identical or virtually identical DNA. Cloning can be either natural or artificial. In nature, many organisms produce clones through asexual reproduction.

On 27 December 2002, a French scientist, Brigitte Boisselier at Miami reportedly disclosed cloning of the first human baby.⁴⁷ It was said to be a girl born by a secret caesarean delivery. The scientist was stated to be the president of the Human Cloning Society, Clonaid and a believer in [Raëlism](#), or [Raëlianism](#), a UFO sect that believes in extraterrestrials (ET) going around in unidentified flying objects concerned about the well-being of humans. There was no independent scientific confirmation. According to the spokesperson, they used the egg of a woman, a

⁴⁶Carcinogens are substances that can promote cancer (carcinogenesis).

⁴⁷"Birth of Girl through Cloning". Miami, PTI News Scan, New Delhi. 27 December 2002.

31-year-old American.⁴⁸ Genetic scientists attacked the “appalling and scientifically irresponsible announcement”.⁴⁹ Most of the scientists believe in therapeutic cloning as opposed to reproductive cloning. The response to the announcement was mixed and soon faded away. The cult is about 100,000 strong (2018). They believe aliens created humans by cloning themselves. The group is led by Claude Vorihon, a one-time racing driver. He tells his vast followers that the aliens will be back on earth by 2035.⁵⁰ It is not long. It is within these parameters of personality and cult behaviour such claims have to be analysed. Cloning, however, is not supported by bioethicists as, according to them, it can cause high incidence of malformations and foetal deaths.

So far scientists have succeeded in cloning sheep, mice, goats, cows, pigs and cats. Cloning produces a new individual using only one person’s DNA. Human cloning for reproductive purposes is banned in several countries. In the process of cloning, a cell is taken from the cloned father, and an unfertilised egg is taken from the cloned mother. The nucleus is removed from the cell. And the egg is stripped off its genetic code, and DNA is removed from the nucleus. The donor cell nucleus is then fused with the egg. The egg is given the donor’s genetic code. Thereafter the cell is developed in a lab until it becomes an embryo. The embryo is then implanted into uterus—simple. The baby will be an exact genetic copy of the donor, not otherwise.⁵¹ It will have the same genes. Genes are only one component of a person’s identity. Environment is a big influence. The clone may well have a different intelligence quotient (IQ) and even looks. That is the easiest and closest one could ever copy a human for living with life induced in it!

According to scientists, the standard tests used for DNA testing were sufficient. But human and animal cells also contain a second kind of DNA outside their cells. It resides in the mitochondria, the power plant of the cell. Some scientists say that this additional DNA is also needed for convincing evidence.

There are serious objections to human cloning. In the United States, the conservatives want an outright ban. The Congress is divided. Many senators agree for therapeutic cloning, but not for reproductive cloning. Cloning may solve intractable diseases, but the White House is all for a comprehensive ban. According to some scientists, it will be hard to clone successfully. It is a step too far for now, though there are identical twins walking around the globe. Clones are not natural. Identical twins are natural clones. Many organisms reproduce by cloning. Did life start that way? If so, cloning is another wine in a new bottle. It is also important to understand that cloning is not a panacea for all the problems the humans face. In fact it could become another problem if not regulated carefully. Unlike popular belief,

⁴⁸Rajagopalan, S. “French Scientist Claims First Human Clone is Born, A Girl”. *Hindustan Times*, New Delhi, 28 December 2002. p. 1

⁴⁹*Ibid.*

⁵⁰“The Raelians”. *Hindustan Times*, New Delhi. 28 December 2002. p. 1.

⁵¹“HTC and Agencies, Cloning Firm to Get Outside Verification”. *Hindustan Times*, New Delhi. 29 December 2002.

clones need not be healthier. It is noticed that cloned animals suffered from premature ageing. If that is so, such a birth make-up will not be acceptable to the clones in show business at least.

There are opinions that cloning should not be banned but permitted under highly regulated conditions until at least the process is perfected. That is a long way ahead. Therapeutic cloning can be regulated under strict guidelines. It can cure diseases. In that, single cells and organs are copied. Reproductive cloning where a whole human is copied needs serious regulations. In the case of Raelians, the purpose of cloning may be different. One has to see the purpose before banning. A ban will drive the technology underground and also from developing into open-source technology. In national security matters, drawbacks are acceptable if advantages outweigh them. The loudest critics of cloning in the world today are conservative religious groups and environmentalists. Scientists are divided; but most oppose outright bans. It obstructs knowledge revolution.

Under this scenario, probably cloning will not become widespread. Besides, the general information about cloning to ordinary people varied. Most of them expect cloning to be the panacea for all the ills of the world. It is not so. Against this argument, cloning also needs not be the source of all problems the world may face in the future as some others believe strongly. It is a subject of knowledge study, and responsible scientists can handle it sensibly for pure purpose of knowledge generation aimed at the well-being of the world. For that, they should have the freedom under regulation to deal with the subject. Most couple prefer mixed genetic offspring. Megalomaniacs may drop the idea once they realise a clone is likely to be a different person. And one does not know whether governments who banned cloning are secretly proceeding with experiments to remain in the mainstream research. Research and policies need not match in a world where confidence generation is not an easy task.

Cloning has varieties of opponents. The procedure is considered to be direct intervention in god's way of engineering genetics from the time when the planet became conducive to sustain life.⁵² It is considered to be better and prudent to leave it that way; they argue. Well, it may not be so, argue others. There is also the third party who find an opportunity here before, even if the world gets into a quandary by their works. They do not care. The question some ask is based on the concept of God. Did God invent and create humans to reinvent themselves or not to bother about it and live it to the God itself? The humans currently do not have a system to verify this. They simply do not know. But the fact is clear. As some believes, genetic engineering is not playing God, because creating life is not the sole purpose of God. It, perhaps, was one of the simplest of all tasks God would have ever performed. But still it is a matter of human concern. Pope John Paul condemned human cloning as an arrogant attempt to interfere with God's creation and tamper it. Technical progress

⁵² "I am against Cloning". Says Kalam". *The Asian Age*, New Delhi. 26 July 2004. p. 3.

improves sense of power in people. Pope made this statement in Rimin, Italy, while addressing a meeting of Catholic cultural, political and business leaders.⁵³

Much is spoken and written about bioethics and bioethicists. It is stated that all living things on earth share the same cell division process stretching back to 2 billion years.⁵⁴ What difference will it make if some more are created by the humans in their intellectual pursuit for a better world? That will become playing God and hence incorrect, some may retort vehemently. “Stop playing God” is what one of the geneticist said. What about those who do not believe in God? According to Sir Alec Jeffreys, the inventor of DNA fingerprinting, genetic engineering to build a better human being is like creating “hell on earth”. The last word in evolution still remains God; added to that is the statement that speciality of human species is its diversity. In genetic engineering, there is an element of tampering with nature.⁵⁵

After a prolonged and often-emotional debate, the United States House of Representatives voted overwhelmingly to ban all forms of human cloning—for the purpose of reproduction as well as research involving somatic cell nuclear transfer (SCNT) techniques. The Human Cloning Prohibition Act of 2003 (HR 534) was approved by a vote of 241–155.⁵⁶ The measure would sentence violators with up to 10 years in prison and impose fines as high as US\$1 million per infraction. The proponents of the Act were vociferous on the issue stating that they could not afford to treat the issue of human embryo cloning lightly stating that human race is not open to experimentation at any level, even at the molecular level. At the same time, human beings were guinea pigs throughout the course of history. The ban proposed is effective only for cloning. The bill had been strongly opposed by the biomedical and research communities but had the support of the White House and many religious, women’s-rights and pro-life groups. This was a lead statement by President Bush Jr. in his ban in the creation of human embryos. The ban has disappointed many who were in favour of human cloning and stem cell research for advancement of medical and clinical procedures. They criticized the ban as a short-sighted one and called it a draconian legislation that will stop the momentum towards the most promising medicine of the human period.

Britain has approved human cloning programmes in scientific research.⁵⁷ That makes it the first country in Europe to approve the use of human cloning for medical purposes. Universities in the country can engage in the controversial issue of cloning human embryos and to use them to create stem cells with this approval. The stem cells produced from cloned embryos will be used to produce material which may

cure some of diseases, such as cancer, Parkinson's or Alzheimer's disease. That will be a great step forward long with bioethical culture. According to bioethicists, therapeutic cloning can harness the power of stem cells to eliminate some of the major threats to human health.

It is only a matter of time, as it seems, the wave of cloning for future health of humans reach other nations.

23.8.3 *Genome and Plants*

Genetically modified crops are favoured in many places and not so in certain areas.⁵⁸ Some of them are not sure. Genetic engineering approval committee or similar committees approve genome modifications. In India, the crops that are genetically modified are many: Indian mustards, Bt cotton, etc. The critics of genetic modification of plants say that gene jumping can cause havoc. GM food may take time to take over. The real fear so far is the ecological imbalance the cross-pollination can cause. People will have no control. But the advantages are higher yield, lower pesticide use, less use of water, fortification to tackle nutritional deficiencies such as iodine, iron, vitamin and resistance to climate change. GM plants may come from bacteria, viruses, other plants and animals.

The *Codex Alimentarius*⁵⁹ has guidelines for assessing risk associated with foods derived from biotechnology. It has also established 50 new safety and quality standards. A multi-donour trust fund has been set up to enable the developing countries to participate more effectively in Codex work. The FAO provides the Secretariat of the International Plant Protection Convention (IPPC), which aims to prevent the introduction and spread of pests. The Convention was amended in 1997. The Rotterdam Convention on the Prior Informed Consent Procedure will help protect people and the environment against hazardous chemicals, including pesticides. The International Treaty on Plant Genetic Resources for Food and Agriculture has provided an internationally binding framework for the conservation and sustainable use of plant genetic resources. The FAO is also currently hosting the Interim Secretariat of the Global Crop Diversity Trust, which aims to ensure sustainable funding for the long-term conservation of crop collections. Finally, the FAO is supervising preparation of the first report on the state of the world's animal genetic resources and the definition of priority actions for better utilisation and conservation of these resources. This report should be submitted to the Conference in 2007.

⁵⁹ Joint Commission of the FAO and the WHO established in 1963 to develop an international code of food quality standards.

23.8.4 *Genetically Modified Consumer Products*

Consumer resistance is natural to genetically modified products. Often the complaint is that scientists play God by genetic manipulation of natural process. These arguments and belief systems cause strong reservations in the release of genetically modified organisms into nature (GMO) since their scientific impact is not known. The impact can be unpredictable, unknown and irreversible, on all living beings on earth. They also oppose all patents on plants, animals and humans as well as patents on their genes. Genome opposers say that life is not an industrial commodity. Every person has right to opinion.

23.9 Periodic Table of Life

In a world that is divided at any point in time on opinion and essentials of life itself, well-being of people cannot be seen in isolation or as insular to individual human being. It is for the group and comes within the genre of well-being of an individual within a group, in this instant, the nation state. Life has to be seen that way and for which the latest in the elements of national security, genomic security, can play an important role if the governments understand its importance to human life by deflecting the mirror of prudence in the best possible way according to changing times.

Genomic studies have opened up life for the world to see. Each cell in a life form is a living entity. A virtual table of life can be prepared by deciphering chromosomes. Genes control the formation of proteins that make cells tick deciding how it will repair, defend or divide itself, packaged in the chromosomes in the nucleus of cells. After the first draft of the entire human genome, the complete set of instructions (that are packaged in human genome) that needed to make a human being was unveiled in 2002. Now the researchers are on unscrambling the chromosomes one by one. Decoding chromosomes lead the geneticists to disease-causing genes and immune system codes. This information will help scientists to understand why some people are more prone to certain diseases (Alzheimer's, Usher syndromes, etc.). This can help doctors to screen patients for their genetic conditions such as cancers and cardiac diseases. People can be warned early and advised to change lifestyles. Someday, abnormal genes can be identified and corrected in the sperms and eggs to edit the very DNA inheritance that one generation leaves behind for the next.

Study of life's periodic table is with interesting finds. The human gene table shows a cannibal gene in them. Does this mean that the humans have depressed forbidden craving for human flesh? The signature found by London scientists points to a history of cannibalism worldwide. The signature is the one that protects one from prions the proteins that can be transmitted by infected meat and attack the nerve

cells of the brain. It is in mad cow disease (1996) widespread in England. But they spread more easily through human flesh.⁶⁰

Watson who discovered the double helix along with Francis Crick says there is no God. According to him, it doesn't make common sense. Therefore genetics may not offend God, so there is nothing wrong with a woman wanting a healthy child. He is one of the scientists who fear political correctness could inhibit the scientist's ability to alleviate human suffering. National security could mean limiting human suffering.⁶¹

23.10 Society and Genomic Security

With increased activism in the genomic terrain, concerns about its use and capabilities are also expanding in society. There are too many ethical, societal and legal issues in genome research and in its applicability. Privacy and confidentiality of genetic information is one of them. The issues are who owns and controls them and how the state and anti-state parties will use the information against the individual. The issues are not exactly similar to medical privacy as practised today. Genetic information will be used in almost all the activities like insurance, schools, employment, etc. How fair these users will be with one's genetic information is another issue. Psychological impact, stigmatisation, etc. in case a disease or the probability of a disease is revealed can be far too serious. Even superstitious belief systems that predict a negative future had made people not only feel depressed but also to ostracise those in the family for wrong predictions from soothsayers, etc. It is only natural that such predictions by a scientifically approved method can cause more serious issues of stigma and rejection that may lead to family and social neglect. Besides, there will be reproductive, clinical, environmental, conceptual, philosophical and serious economic issues that may end up in commercial aspects of genome research. But, the fact remains that knowledge has the right to spread, and when it spreads, many systems based on lack of knowledge will crumble. But so far in human experience, knowledge has not harmed the society except for its negative use. Even then knowledge is available for countering the damage that is caused by abuse of knowledge itself. Pessimism has a place in national security because it is certain that pessimists may look for precautionary measures. Optimists don't heed to them. Hence a bit of pessimism, under this argument, seems to be acceptable.

Ethicality is the overwhelming question. It could be voiced from all angles. What about the modified super tomato that could withstand extreme cold and last longer than other tomatoes without rotting and a bit more nutritional? Does it taste fishy? Will religious vegetarians discard it? It shouldn't even if it contains a piece of genes

⁶⁰“Humans have a Cannibal Gene”. *Hindustan Times*, New Delhi. 12 April 2003. p. 12.

⁶¹Khanna, A. “Genetics doesn't Offend Gods as There Seem to be None”. *The Asian Age*, New Delhi, 26 April 2003, p. 8.

from a cod from the northern Atlantic waters. Ethicality of cultural variation can cause serious problems and bring the world back to the period of the World War I when people were identified by races. Hitler's *Mein Kampf* is full of praise for the pure Aryan race and the real blood people who only have the authority to rule and even exist in the world. There is also another view in history that the concept of Aryans is a myth.⁶² That is where distortion in history makes history. All these can come back to haunt the humans one day with scientific sanction in the background. The genomic security issues are to be seen from these viewpoints.

23.11 Challenges to Genomic Findings: Beyond DNA?

In spite of the euphoria and the hoopla-braced controversies, it is not clear whether the genome-induced perspectives will end up in a whimper at the end of the century. There are many unexpected findings in store for the expected. Geneticists from Purdue University have claimed that they had found genes in certain plants that are corrected for defects inherited from earlier generation.⁶³ That is against the DNA theory. The conclusion of such a find is that some organisms may hold a cryptic backup version of corrected copy of their genome that bypasses the usual mechanisms of heredity discovered by Gregor Mendel (1822–1884).⁶⁴ What is important here is that the new substance, the cryptic genome, does not seem to be made of DNA. If it is true, our friendly and hopeful DNA will lose a couple of points in the first set. The result has been found in a mustard like plant *Arabidopsis* favoured by plant geneticists. In the research, the scientists found that a mutated gene has changed. The change in the gene occurred by change in DNA units back into the normal form. It was a shock, more than a surprise. Such a change is possible by many ways, but not without a correct copy of the gene as a template. The scientists were of

⁶² Danino, M. and Nahar, S. (1996) *The Invasion that Never Was*. The Mother's Institute of Research. The book explains the noting in history about the Aryan invasion of India as a myth. However the author would like to clarify that invasion of India by outsiders was true to the best of knowledge. Those who came from northeast over would have been historically distorted as Aryans (for specific reasons which are only a guess). They were called by the term Aryans. According to it, Aryans were with white skins because they came from the relatively cold and melanin-deficit countries. White skin is considered ethnically superior by those who had white skins along with power. The term Aryan by Adolf Hitler is an example. For the author, the term Aryans indicate there were also others in India. So the invasions were between inliers and outliers all the time. The population in India today should be seen as hybrid in partial measure of both. And, thereby India may be a paradise for genomic studies.

India

⁶³ Wade, N. "New Gene Find Challenges Theory of Why We Need Sex". *The Asian Age*, New Delhi.

24 March 2005, p. 4.

⁶⁴ Austrian botanist and plant scientist who was the first to lay mathematical foundation for genetics. It was called Mendelism.

the opinion that RNA, the unstable, but close cousin of DNA, must be responsible. RNA performs many hereditary functions in the cell, and it is the building material for many viruses. The RNA would have been responsible when the plant was under stress to change the code to correct the gene. The hypothesis is about RNA backup genome, lying undetected. In this case, the cryptic template, if existed, should be more resistant to mutation than the DNA it helps to correct. But normally RNA accumulates more errors when copied by the cell.⁶⁵ This report brings a new question, “Is stress the kiln that bakes DNA?”

This finding, if proved right, will cause an exception to Mendel’s laws of inheritance. The DNA sequence itself has changed. This will also undercut the theory of sex to prevent mutation. But the self-correcting backup system poses a serious question in the journey to make a life in a way humans are not used to.

23.12 What Is a Human in Genomic Appreciation?

This is a key question in this study. Who is a human anyway? In the genomic appreciation, a human is a “form of life” similar to all other cellular life forms evolved on earth through natural process by genetic inheritance from previous life forms in an exclusive and sequential order, where inheritance means biological inheritance of parental characteristics of heredity sexually or asexually.⁶⁶ The process of biological inheritance is identical for all living forms and is in no way different for humans. As such humans cannot be differentiated from other life forms based on the genomic configuration of life. There is no difference except for the stage of evolution, which this study considers advanced only by the time of birth and subsequent developments which is also applicable to other life forms in their respective taxonomical projections strictly for comparing within themselves and not with other life forms in the process of life. This statement is made under the observational belief that passage of time can make a life form more advanced genetically by evolutionary surge not in taxonomical comparison but within the space and boundaries of its classification as a life form. This is based on the assumption that evolutionary shift of a life form from one to another in taxonomical superiority. Humans are comparable with other life forms and among themselves by the time functional stage of natural evolution by genetical development that will reflect relatively as more advanced or less advanced in their somatopsychic personality among the taxonomical classification of species and as humans themselves. For the purpose of this statement, hereditary information is that information contained in the genes carried on chromosomes in the nucleus of a living cell.

⁶⁵ Wade, N. “Stem Cells Opens New Vistas”. *The Asian Age*, New Delhi. 19 September 2002. p. 17.

⁶⁶ Author’s find.

Under the taxonomic principles of coordination attributed to Carl Linnaeus (1758),⁶⁷ this study considers present-day humans as *Homo sapiens-sapiens* as a lectotype⁶⁸ specimen of subspecies that stand alone. This classification is not seriously relevant to the study of national security. *Homo sapiens-sapiens* thus becomes the subspecies of *Homo sapiens* that consists of the only surviving members of the genus *Homo*. This subspecies description is used to differentiate the modern humans from more archaic members of *Homo sapiens*. There are debates whether this term is necessary as humans are the only subspecies as *Homo sapiens-sapiens*. Such subspecies differentiation is introduced only when there are two or more identified subgroups according to taxonomical practices.

These arguments lead to what this study has to say about humans in terms of governance by national security. The recommendation here is the usage of the term *sapiens* to strategically differentiate present-day humans of the second decade of the twenty-first century accepting the human needs and wants for a more responsible and advanced period in the future provided they want the concept of national security as the cornerstone of human well-being under appropriate governance mechanism to maximise it in a more responsible and advanced manner. This study considers the time, post Covid-19 and entry into 2020 the second decade of the twenty-first century, is appropriate to show concern for fellow humans at least outwardly as it is not easy to overcome survival emotions in the unitary human civilisation. Changing the millennia old survival behaviour patterns is not easy for humans, but the Agenda 2030 and other sustainability instruments will not function effectively if humans stick to their primordial and primitive behaviour hang up to move forward. The world is cleansed and sanitised by the last of the pandemic so far, the Covid-19, in the 5500 years or so of known pandemic history since the first recorded one so far for a better, healthy and aware human generation. It was visible in the responsible manner (with the usual disorder and riff-raff behaviour) the human system handled the pandemic, compared to similar incidences in the past. The human system is genuinely and increasingly becoming concerned about the well-being of all showing a sign of matured appreciation of sustainable living to ensure a quality future for the generations to come. That's why the author quoted "War is over" in Chap. 9. There are many evidences in human behaviour and personality that point out positive changes in global human thinking which will require close observation and analyses. The world seemingly is getting on to a new track that may lead them to a better more humane life. The world is heading to a no-war situation. But the other-than-war

⁶⁷Carl Linnaeus (1707–1778) was a Swedish naturalist and explorer. He formalised binomial nomenclature, the modern system of naming organisms. He is known as the "father of modern taxonomy". <https://www.google.com/search?client=firefox-b-d&q=Linnaeus>. Accessed 25 January 2021.

⁶⁸A lectotype in zoology is a specimen or a kind of name-bearing type selected to serve as the single-type specimen for species. When a species was originally described on the basis of a name-bearing type consisting of multiple specimens, one of those may be designated as the lectotype. This will reduce the potential for confusion.

situation will certainly be conflict ridden as humans need violence by design as survival prerogatives. This is especially so in the absence of war.

The improved human in this context envisaged in an abstractive format for the time being in this study with utmost hope and expectation of becoming a reality in the future is not the taxonomical *Homo sapiens-sapiens* but simply an arbitrarily perceived advanced version differentiated by sheer responsibility towards fellow humans—the sapien human. This study in all means is for the sapien humans among the present-day humans that they alone can become by determined differentiation without waiting for neither genetical nor taxonomical fast tracks. Therefore the present-day *Homo sapiens-sapiens* will have to become a sapien human by defying the law of invariance and the law of limitations honing and using their intellectual survival tool, which is the best of all survival tools in the living world. The story of sapien human a.k.a sapien is discussed further in later chapters.

The confidence of the author in giving an advanced name to a species with intellect prior to its evolutionary advancement is with the hope to make it advance faster in a reverse manner. To make a genomic advancement by sheer effect of feeling it—by behaviour modification as a catalyst or prompter for genetic change on fast track evolution which the author believes—is possible for the thinking life forms. Only the sapien humans qualify for it compared to others on a relatively faster track. The intellectually powered humans and their systems can advance genomically if favourable environment is provided by maximum governance and individuals appreciate the fellow humans and generations to come in new light of total well-being.

23.13 Bioethics and Genomic Justice

Ethical practices in governance related to genomics could fall within the larger concept of bioethics and the overall topic of ethics and human systems or can be contained within as genomic justice. To that extend bioethics is a larger subject (Box 23.5) that deals with all aspects of biology and medicine as applicable in human behaviour and conduct in a human system that is advanced and progressive in intellectual tolerance and concern for self and fellow humans. This is a vague definition but considered appropriate for this study which in this chapter looks at the ethical practices related to genomic security in governance. Deductionism in ethics helps in framing rules and regulations and also drafting and legislating legal aspects in governance. Genomic security can invite a host of ethical issues in governance that will demand executive prudence while policymaking.

Box 23.5: So, What Is Bioethics?

“Bioethics” is ethics related to biological studies and practices, where ethics is the changing human perceptions relative to life and associated direct and indirect interactions acceptable to the members in a human system for harmonious living. It involves many activities traditionally and customarily evolved including deliberate practices to avoid conflicts among competing values and goals. The ethical question is, “What should one do, all things considered, when it appears in one’s activity and interaction in a situational context?” When the questions of ethics are applied to biology, health and medicine, the involved people may consider the maximum well-being of all humans in the system in the context of the activity and its outcome sans vested interests. Bioethics therefore forms a part of the larger concept of ethical studies. It may have further subdivisions in terms of genetics, biomics and any other matters of life as it evolves. Ethics and its derivatives such as bioethics are for all humans to practice and therefore an integral part of human governance. The areas within bioethics include health policies of government, health education, genetics, physiotherapy, clinical ethics, sex therapy, psychiatric consultations, medical tests, organ management, disability management, geriatric relations, palliative care, genetic research and practices, biological issues, medical and biological privacy of individuals, neuro-ethics, precision medicines, ethnic concerns, clinical neuro-ethics, reproductive ethics, medical research ethics, social health detriments, mental health treatments, epidemic and pandemic treatment and containment policies, biomic ethics (more in future) (Chap. 24) and so on.

There are references to ethics related to governance and social systems elsewhere, including this chapter, in this book. Ethics is a human aspect which is in the eye of the responsible and concerned. A government is supposed to be both considering the power it has been delegated with.

Being a recent addition as an element of national security, genomic security will require balancing with justice and governance, especially related innovations and applications. Genomics, since 1990s, have been very much a thing in governance. The HGP (explained earlier) can also be said as the harbinger of genomic justice and ethical practices in genomic security. It had also invited controversies (genomic development of seeds, objections from eating a vegetable that has non-vegetarian genes such as a tomato developed with genes of Atlantic cod from the cold deep waters of Maine so that the vegetable can withstand strong cold while in storage and transportation, etc.), serving genetically modified (GM) item to unsuspecting others, etc.

The HGP (1990) was followed by various other efforts in genomic research and application. These included the Human Genome Diversity Project (HGDP), the International HapMap Project (IHMP), the Icelandic company deCODE genetics

and Generation Scotland, a national biobank of donated tissue.⁶⁹ In the new century, there were new genomic research and corporate organisations on personal-genomics and medical-data-sharing initiatives and even do-it-yourself biology organisations. An example was DIYbio.org.⁷⁰ The DIYbio.org claims a code of ethics to follow in practice and progress. These developments show that genomic security as an element of national security is spreading similar to an inkblot within a human system that is more participatory and diverse in genomic aspects under transformed conceptualisations of governance and privacy, including self-governance.

But the trend in genomic issues is towards a system that may cause problems to governments as players and stakeholders may get involved into many ethical issues associated with biological sciences. This may overlap into other elements of national security such as health, food, environment and so on. Holding the bull by its horn will be easier if it is standing still. Hence, genomic security may be ethically bound and legally framed to avoid before it gains speedy momentum to avoid disastrous consequences that may upset the laws of nature, the guardians of the building blocks of life and their molecular structures.

Corrupt practices, disputes, ethnic allegations, identity theft, genomic wars and conflicts, resource equity and various other factors never seen or heard earlier in society can be collaterals to “freedom” in genomic research. This is an area that the government may regulate leveraging on bioethics. Ethics will be absent in the business of DNA especially when ethics is not in the DNA. This is where the government needs to examine its own DNA for ethical governance.

Many governments may frame initiatives without considering ethically correct aspects. This trend may impact genomic security more seriously than other elements. There are many studies on ethics in research involving humans directly or indirectly. In genomic research, the ethical aspects will have direct effect in what is called genomic justice (Box 23.6).

Box 23.6: Aspects of Bioethics in Genomic Justice: A Wish List?

This study identifies certain aspects of promoting ethics and justice in genomic security that may include the following:

- Educating people in the respective social systems including those in government about the need to understand the importance of human life and aware of it keeping oneself at the centre of the system in a responsible manner.

(continued)

⁶⁹Isasi, R. “Bioethics: Justice in genomics. *Nature* **551**, 296–297 (2017). <https://doi.org/10.1038/551296a>. <https://www.nature.com/articles/551296a>. Accessed 20 January 2018.

⁷⁰Publicised as An Institution for the Do-It-Yourself (DIY) Biologist, in 2008 the group claims a mission of vibrant, productive and safe community of DIY biologists under the belief that biotechnology has the potential to benefit everyone.

Box 23.6 (continued)

- Make people responsible for the safety and concern of others in their own system.
- Opening up genomic science for the people under the do-it-yourself structure with support and ethical surveillance by government in a serious manner ab initio.
- Governing under and also to ensure utmost transparency of the genomic programmes.
- Sharing of genomic research and information for knowledge management and also where safety and security of people may be affected.
- Decentralise science under citizen science principles.
- Universalise the study of humans in every topic to avoid people gathering around improper knowledge on genomics and life sciences.
- Understand the subject is deep and one need support from the more knowledgeable people for correct practices in genomics.
- Be alert and aware of the community and their safety all the time.
- Use genomics for peaceful coexistence in the human system.
- Develop mutual respect.
- Depend upon self-responsibility.
- Remain accountable to society all the time for one's own deeds.

Genomic security will demand constant and specific attention of governments not only in deciding bioethical matters but also introducing regulator regimes nationally and internationally. There are many issues such as do-it-yourself genome practices (Box 23.7), biohacking, newborn genomic screening, sharing genomic data, securing genome and economic data, covert genomic manipulations and everything that happens in human mind as in other terrains and also those exclusive to genomic space. The issues are waiting around the corner; some of them still being attempted. The sapient humans may be able to resist the temptations once they are aware of the ills associated with their actions.

Box 23.7: What Is Do-It-Yourself Genome Policy?

Do-it-yourself genome policy (DIYGP) is dealing with genome, one's own or those of others for the purpose that the doer decides. There can be many arguments moral or otherwise for an individual's right to access a genome. There will be policy implications in governance which will also demand new genomic laws.

Many bioethicists and researchers engaged in genetics and genomic studies express apprehensions on genomic privacy (GP) of individuals. There are risks, including breach of genomic privacy of individuals, the result of which could be much more serious than those related to privacy of personal information. The

apprehension seems to be real as a threat and is quite likely to be termed as genomic security. But genomic security is not about genomic privacy. The meaning of genomic security as an element of national security is different from the issues of individual genomic privacy. The element of genomic security is a matter of national security governance and includes genomic privacy also. There are many unexplored and less-explored threats to human genomic makeup which includes threat of digitized genomes being altered with dire consequences in medical or legal settings.

23.14 What if There Is More Than DNA to Life?

The author is rather hesitant to ask this question. He is not competent to ask such question. But in governance, one could be curious beyond one's knowledge level. Enquires are on to locate life in deep space. There are studies that are more or less pointing towards deep space as the cause of life on earth. Only recently (relatively) the humans have been able to identify DNA as the cause of life that humans are familiar with. The familiarity is the prime reason they could identify DNA as the cause of life (they are familiar with) through research. Research is always on something familiar, not something unknown. Research continues further on the unknown once it becomes familiar. Therefore, since one knows about DNA and its relationship with life, is it possible to examine whether there are other life forms beyond the much talked about DNA? This question is necessary to get out of the subliminal fixation of humans to DNA. DNA has become even a term used in organisational theories. That is absurd.

And, if there are non-DNA life forms, can't they be creeping on Earth also? Can memory keeping minerals (silicon?) create life in another form? Will humans ever encounter a non-DNA life form? Well, what about the virus that the humans consider "not alive?" Can't it be a different life form? Say the tobacco mosaic virus (TMV)? If that is so, one has to establish that there could be life forms whose base is not DNA. Such arguments may lead humans to enquire about non-carbon-based lives. In such case, can one conclude the answer is "no", because there are enough evidences to say every life has to be carbon based? But the question can become more interesting when those who want to argue that DNA-based life forms too are different from each other in their energy assimilation. The life forms that humans are familiar with survive on oxygen, carbon dioxide and none of the two. The amazing archaea (very distinct from bacteria and eukaryotes) can turn iron into meat—inorganic into organic, and much more.

As far as humans can see, all the self-reproducing cellular organisms are DNA based. DNA is the genome. There are organisms without DNA; they carry RNA genome. Scientists see plausibility for the existence of an RNA world much before the DNA world came into sight, in the microbial regime. Biological diversity among DNA-less microorganisms is vast. But it is important at least humans decide whether they have to bet their entire life's savings on DNA when it is about life. For that one has to repeat the question.

It is not just about DNA hunting in deep space. The process could lead to something else that hasn't been in the agenda. That is how science works under human intelligence. What we can conclude about life is that it is not just a planet based. The universe is its home.

The happenings in the universe about which humans have limited information so far are sufficient enough to conclude that life had more varied beginnings and forms that could make what the humans know today about life look infinitesimally small—almost nothing. And it doesn't follow the evolutionary path that life took elsewhere (if we discover it) must resemble that of the earthlings. What does that mean?

All these show life is still a mystery to humans; that means to life itself. There is no consensus on life yet. This is more so because it is life that is attempting to find out about life. So, the question what if there is more than DNA will remain a quest forever for humans. It should not in any way affect the study of humans interactively governing humans.

23.15 So, What Is Genomic Security?

Genomic security, in this study, is the 15th identified element of national security in the chronological hierarchy of 16 elements. Genomic security, “genosec” in short with the allotted symbol “ g_{s2} ” is a fast developing element of national security that is expected to gain importance exponentially in the present century. Genomics, according to scientists, hold high potential in human well-being under responsible governance. The contention is that genomics is a kind of high value biocapital. Governments under responsible governance can turn around genomic security to its real sense of human well-being in many different ways that has never been experienced by the humans so far.

Genomic security is the only element in the terrain at the moment and most probably for some more time. It is interactive and integrable with all the other terrains and elements.

23.15.1 Definition: Genomic Security

Against the background of this study, genomic security means “the capability of a nation to effectively understand, appreciate, regulate, communicate and utilise the value of genomics for human well-being in a responsible and value based manner within the national and global context by governance, perfectly aligned with the other elements of national security and integrated with all the terrains of national governance”.

23.16 Summation

The biggest surprise in genomics does not come from the facts that today the humans can probe into irreversible time to identify their parental origins, one can read oneself like a book one day, one day the humans may not have a disease that cannot be cured, or they can replicate and perhaps transfer memories into another like transferring into a micro vault in a computer. Considering the potential of genomics, the surprise is still an unpredictable distance away. Genomic is about the parts that contain instructions about how an organism builds, operates, maintains and replicates itself by responding to environmental demands externally and internally. But there is a long way to go. The knowledge the humans have today may perhaps take more than two centuries to mature into serious genomic world. In the meantime, therapeutic potential of genomics has achieved an early phase in the commercial sector. Translating genomic knowledge into health benefits will be the commercial approach towards human health. Advancements in various other fields like colonisation of planets elsewhere in the terrain of outer space and beyond may materialise for which genomic revolution also may pave way. Or the world may meet further disasters in the other elements of national security that may end up in system collapse calling it a day for the humans. The Olduvai lifestyle or total annihilation for the human race before the genomic revolution mature can cause serious limitations. Chance plays an important role, because everything in the world seemingly had a situation when chance became the only tool that created it. One doesn't know—chance lurks in this statement too.

Genomic research cannot progress without advanced computing technology. Towards that extent, it is depended on cyber security quite seriously. The requirement today for cyber-related expansion in biological research is far less than the demand on it. Computational tools are required seriously. The course of biological research can undergo fundamental and radical change only if advanced computing methods are available. Hence it is part of genomic studies and research. The viewpoints on genomic research have far-reaching results. It is not restricted to health alone. The knowledge gained from genomic life can be used to produce energy, remove or inactivate toxic contaminants, store carbon to mitigate global climate change. These are besides food processing, pharmaceuticals, separations and production of industrial and other chemicals.

Genomic security fears impact on privacy, duplication, criminal activities and danger of mutation. The supporters say it is scientific, ethical, morally correct and very valuable for humans in their well-being. Importance of genome, barring all the exceptions of ethics, moral aspects and disaster syndromes in case the experiments go out of control and the terrorist and criminal angle is one of hope to humankind. The prospective areas are mind-boggling and can seriously support the well-being of the people. The potential areas include:

- Elimination of congenital diseases
- Cure for terminal diseases

- Coagulants from genetically modified organism to treat haemophiliacs or gunshot victims⁷¹
- Handling biowastes
- Biotechnological advancements
- Genetic modification of high yielding food varieties both plant and animal species yield that can revolutionise food security management
- Cure for special diseases like the Alzheimer's

It is interesting to note at the end that every life is extinguished by a failure that at that moment becomes the pressure point. For the legendary Greek hero, the greatest warrior ever born according to Homer's *Odyssey*, *Achilles*, it was his heel that proved to be the pressure point. By a strange coincidence, Lord *Krishna*, the hero of the Indian epic *Mahabharat*, also died when an arrow of a hunter mistakenly struck him on his heel. (Considering the antediluvian relations that India had with Greece, the similarities may not be strange, though). Another hero of the epic *Karna* (*Karan*) was invincible till he had his armour on his body. The armour here is symbolic protection of his chest—the pressure point. It was similar to the long locks of the Israelite hero Samson.⁷² There are many such examples in mythology. The superheroes that everyone is until death knocks at the pressure point have vulnerable spots, and it is these points that cry, “give it to me please, God slipped there”. Stem cell research, through individual medicines, can just undertake that—that is where hope lies.

Irrespective of the issues of resistance in genetic research, there is evidence of off-the-limit researches based on controversial techniques from patent applications. According to report, the United States tops the list followed by Japan, Australia and the United Kingdom.⁷³

Life, especially human life, is a high potency activity. It grows even in almost alien environments. Human life dominantly persists for survival and is not likely to be wiped out or erased out of the planet by any known catastrophe. Genomic science may not be worried to keep life going on the planet. It may certainly help to make it better. To that extent genomic security dangles between life and death to guide it towards making the passage better.

There is a question this study would prefer not to ask loudly. That is about concluding that life started here in human backyard. Isn't it a bit presumptuous? Also, will genetic sequencing alone, in deep space exterior to the planet, resolve questions on life if there are life forms that are not DNA based? From the point of governance by national security, whether such questions are relevant or not will depend upon the strategic national security doctrines of respective governments.

24.1 Introduction

There is an amazing world invisible to human eye but absolutely crowded and dynamic “on and inside” the body of each human being. Each one of those worlds, though characteristically in the same format, is uniquely personal. The individual cannot see this magnificent site of creepy crawlies of the Empyrean world, the

human microbiota,¹ covering the surface and interiors of the body directly. If they could, they would not be able to recognise themselves in a mirror. Ever “seen” a person with his body covered by friendly bees? It is permanent with human microbiome. Human eyes, it looks, are designed only “to see what they should see” to survive within a predetermined spectrum.² Or, rather, just what is necessary to survive the ordeal of life. There is a kind of minimalism by default leading to human limitations. The invisible microbiota is friendly living things mixed with the hostile ones that live on and inside the human body. They could also be genomic accessories or actual facilitators of the human factory. A lot need to be studied about the inhabitants of this mysterious world (Box 24.1).

Box 24.1: Humans Don’t Know

The highlight of the fact is that humans still don’t know much about the microbiota they carry from birth to death and a bit more. That’s one reason the governments are asked to take over “m_{s2}” seriously in governance as it has tremendous potentials towards maximising human well-being. If the government does, many nations will stop caesareans in delivery. That action alone may save billions in health security. Presently research on bacteria is somewhat advanced compared to other microbiota.

The caveat here is that this perhaps may be the first book that advocates human microbiome as an element of national security in national security studies. It is based on the author’s concept. The author is serious about it. While microbiome is about life as a whole in a kind of “life-on-and-in” format, the scan is only over human microbiome which probably may draw the attention of integrating with national security governance. It is also done in the belief that microbiome as a twenty-first-century subject will spread out in an inkblot fashion over other species also in a symbiotic³ fashion by minimising adverse interactions and maximising benefits. This study being in the introductory phase has reserved opinion only on human microbiome but strongly feels it may extend to animals and plants in the future as animal microbiome and plant microbiomes giving scope for two more elements of national security.

The first step here is to understand the two terms: microbiome and microbiota. They are different but together in this study (Box 24.2). Microbiome is the collection

¹The term “microbiota” explains the “ecological communities of commensal, symbiotic and pathogenic microorganisms” found in and on all multicellular organisms studied to date from plants to animals. Microbiota includes bacteria, archaea, protists, fungi and viruses.

²This is a general statement and contrary to the previous study on genomic security. Humans are advancing in evolution. That means genetical also. An example colour discrimination. Humans could not appreciate colour differences in the long past as they can do today. The blue colour was not known as they could not discriminate it in the spectrum. The sky was grey for them. In fact present-day humans can discriminate more colours in the visible spectra.

³Living together of unlike organisms in a mutually beneficial condition.

of genomes from all the microorganisms in the environment, whereas microbiota usually refers to specific microorganisms that are found within a specific environment (Box 24.2).

Box 24.2: Microbiome and Microbiota: Together But Different

Microbiome is the collection of genomes from all the microorganisms found in a particular environment. Every living thing has microbiomes. They can be generalised to their entire organism or broken down into specific microbiomes for different locations on them. This chapter is about microbiome specific to humans for the attention of governance by national security. Microbiomic security is an element of national security in the microbiomic terrain. The element may gradually expand and cover other life forms as it evolves relative to national security governance. That also means microbiomes are individual to each organism. The differences in microbiomes between individuals as well as within the same individual vary, sometimes quite considerably. The microbiome makeup of a person keeps changing. Each human has unique microbiomic signature.

Microbiota refers to specific microorganisms within a specific environment. The term can apply to all the microorganisms found in an environment. There are localised differences in the microbiota of each individual human. It depends on where the microbiota is in the body. For example, the microbiota in the gut of a person can be different from that on the skin. Microbiota therefore has to be referred to the individual as well as the location in or on the individual.

It is also important to know that both the terms are occasionally used interchangeably.

The microbiomic entities work more seriously than the likes of the slaves of the realtor of an ancient Egyptian Pharaoh land. They could catch a few winks or grab a meal in leisure away from the whips and lashes while rolling square stones to the site of some pyramid meant to pickle the dead in sand and stones. Unlike them, the micro-companions in and on the human body do not rest in between. Humans know about them but haven't thought seriously in making them part of national governance for governed human well-being. Governance is yet to enter the terrain realm of the microbiome strategically. Otherwise every aspect of human life has been covered in the modern-day human system governance aimed at national security as perceived. Interestingly, no life form can continue sans its supporting microbiome, including humans. Every human is dependent on his or her distinctive microbiome—the microbiomic signature.

Why did this happen that way? Does the microbiome control life? Whatever, the unseen micros⁴ are not bothered. They are united to share their commitments to human health, very silently.

Actually human microbiome is taken as the genome of all microbes in and on a human body. In a different way, the microbiota could be expressed as part of human anatomy as an exclusively linked rather spread-out organ. It serves necessary functions like any other organ. This will be understood when human body is appreciated as an ecosystem, as part of the environment. They exist or reside (no, not as a tenant, refugee or unlawful immigrant) as part of the human body.

But there is a difference. In the application of human microbiome as an element of national security, this study considers them in a different dimension, not as part of human anatomy. They reside in select niches of human anatomy as differing communities in and on the living body space. It is not only an element but also a terrain, as recommended in this study. The dual specificity is necessary to appreciate the human microbiomic applications as an element in one way and as a terrain of its own in another way. This has been already seen in cyber security and genomic security. Human microbiomic study needs the attention and the appreciation of governments in the world over. Certain changes can take place in this process. It is also possible that the terrain of human microbiome develops further inviting additional elements. The terrain is close to the genomic terrain and may even merge with it briefly or for a longer period. It is not advised, though. It is advisable for terrains to split rather than amalgamate in national security governance. It provides a larger canvas or domain extension for application of elements as human systems are evolving not devolving. Therefore the recommendation is for terrain integration, not dissolution or isolation.

One may count if time permits about 100 trillion unseen friendly teeny-weeny biomicros in a human microbiome, carried permanently in and on an individual. They, it is said, contribute to 2–3% of total body weight and count ten times more than the body cells. Is it a big count? No, but, sufficient under the law of nature. 100 trillion is not a big number in a micro-world of biota or a macroworld of infinitely vast multiverse. Anyone can say the number is not accurate. The author looks at numbers with zeros after with a bit of scepticism. More so, if the zero-count keeps increasing, he has this fad that the number of zeros after a digit is indicative of the accuracy of the statement. From this point of view, a particular human microbiome will have a lot of microbes that are not countable as of now with the patience of a fidgety child. Microbiota is location specific in and on a human and its function. It is not absolutely clear now. Human microbiota is said to develop the host in matters of organ morphogenesis, metabolism, aging, behaviour, colonisation resistance, nutrition, pathogen protection, maturation of the immune system and more. That means there are too many biomicros controlling human life through some serious charter associated with human survival. And, if they are needed for life, they

⁴A term of convenience used for this study to mention an individual microbe of the microbiome. They are normally sized in micros. Micros will have different meaning in other studies.

could be playing a substantial role in matters of human well-being. If that is so, they are required to be taken seriously in governance, not just restricted to scientific labs or pharmacy talks. That again means it's time to look at human microbiomic security seriously.

Attention on human biome perhaps could be attributed to the Russian zoologist Élie Metchnikoff's (1846–1916) suggestion in 1908 to enriching the food with *Lactobacillus* bacteria considered beneficial to the human gut. The subject developed further when Cannon introduced compositional changes in the gut flora by diet in 1921. It took a long time further down the line. The existence of human microbiome was seriously recognised in the late 1990s. Simply put the human microbiomic security is the subject of the new century in national security that is recommended to be introduced as an element as well as a terrain. The scientists consider there are 44 trillion microbial cells in men and 38 trillion in women (2020).⁵

24.2 Microbiomic Security: Setting

The microbiome is the community of microorganisms or microbes living together in a particular habitat or environment, whether living or non-living. Living habitats of microbiomes are humans, animals and plants, as the explorers differentiate senior life forms scientifically. Examples of non-living habitats of microbes are soils, ocean, rocks, buildings, etc. everywhere. In fact the whole planet is swarming with microbiomes or life in its raw form. Astro scientists find it difficult to think the rest of the multiverse is devoid of microbes. They also believe the insignificantly tiny darlings they can't see direct even on a blind date came from the outer space to the planet, humans call earth, and lit the light of life 3.5 billion years back, take or leave a couple of millions just to feel casual. They are not only multiplying but also transforming since then. The transformed life becomes habitats for them to live and work as resident interns as if their job of building life has only started. Stopping them will be impossible. It also means destruction of that life form who attempted it. They can't live without them. So, it is a matter of simply biotic for humans, rather symbiotic.

To understand microbiomic security, the difference between the terms used is to be appreciated. Microbiome refers to the microorganisms and their genes. It also means the terrain of microbiomes identified for the study which could merge with genomic terrain or affirm itself or expand further. The chances are more for the latter. Hence, it is taken as it is. Microbiota refers to the microbes themselves. Then there is

⁵Grasin, D. A. (Ed.). (2020). Neugent, M.L., Hulyalkar, N. V., Nguyen, V. H., Zimmermann, P. E., De. N. J. "Advances in Understanding the Human Urinary Microbiome and Its Potential Role in Urinary Tract Infection". DOI: 10.1128/mBio.00218-20. Nisco <https://mbio.asm.org/content/11/2/e00218-20>. Accessed 1 January 2020.

the metagenome which is about the genes in the microbiomic environment, and their study is known as metagenomics. There are more such terms. This study occasionally uses the terms *micros* or *microbes* in a generalised manner referring to the biology related to the study of microbiomic security.

This study limits discussion on microbiomic security, as of now, in the governance of human microbiome, the microbial community that lives in and out of human body and their integration with national governance along with other elements. It is a complex community that can substantially contribute towards human well-being as a separate element of national security. The microbiota could also cause harm according to some studies.⁶ But, humans need their share of biomicros for existence. In that case, can there be designer micros? Well, this study leaves it to the experts.

The topic is a standalone element in a separate terrain that has close interaction with food security, health security and genomic security besides others. Obviously, it will be interactive with all other elements without being part of any of them (one of the conditions). It is also important to understand that the more the elements an element of national security interact with, that much vital it becomes and appropriately the governance system advances in the country. One of the ways to appreciate the effectiveness of national security governance in a country is to check the degree of interactiveness of a singular element with other elements in the process.

The human microbiome is taken singular in the governance concept. It comprises all microbiota existing within human tissues, biofluids and anatomical sites such as the skin, throat, etc. everywhere. The interesting aspect of human microbiota is that they are acquired at the time of birth⁷ and during the preliminary year of life. They remain with the individuals as a kind of caretaker and concierge in one for the rest of their lives. They do undergo changes during the process of individual life based on environment and lifestyle and carry out many critical tasks for survival of the individual. The microbiota is a complex human ecological community. They could be more complex than human genome itself.

⁶Da Silva, G, and Domingues S. (2017). “We Are Never Alone: Living with the Human Microbiota”. *Front. Young Minds*. 5:35. doi: 10.3389/frym.2017.00035. Accessed 24 June 2020.

⁷The time of birth is basically about the passage from the uterus and subsequent acquisition during and immediately thereafter through various processes. Strictly acquisition of biota starts even before birth. There are increasing evidences that suggest bacterial colonisation starts in the utero—gestational age until birth. D’Argenio, V. (2018). “Human microbiome acquisition and bioinformatic challenges in metagenomic studies. <https://www.ncbi.nlm.nih.gov/pmc/articles/PMC5855605/>. Accessed 09 July 2020.

24.3 World of Human Microbiome

A biome is a collection of flora and fauna in an ecological system at the macro-level. It is everywhere. The world is a biome. The living planet is living because it is a biome, a community of plants and animals adapted to the environment they are living in. Or rather, they are there because the environment exclusive to the planet facilitated life. They have common characteristics with respect to the environment. Biomes in such sense can thus be taken as a universal biome or selective biomes based on climate and environment such as tundra, forests, deserts, savannah, taiga, ocean and so on. Biome is a sign of existence of life.

The world of microbiome is similar. Except that they are as tiny as microbes living collectively as flora and fauna of the microbial world. They exist all around humans, animals, plants, soil, water, air, space, food, liquor and so on. There is also microbiome on and in dead bodies and fossils. There are also synthetic microbiomes created scientifically in the laboratories by genetic engineering for specific purposes. In general every life form, human and nonhuman, has microbiomes on and in it and that continues also after the body is dead. Microbes are the oldest form of life on the planet. The microbes were on earth for about 3.5 billion years as if waiting for other life forms to come. That is provided the microbes are considered life forms; if not, it can be said that they waited patiently and created life on earth.

Symbiotic interaction between living things can create typical situations and outcomes: commensalism, mutualism, amensalism or parasitism.

- In **commensalism**, members of one species (commensal) get benefitted while the other (host) neither gains nor loses by the interaction. The other species is mostly unaffected.
- In **amensalism**, one species is harmed, while other species remains unharmed.
- In **mutualism**, both species gain by interaction.
- In **parasitism**, one benefits and the other harmed.

All these are common in the geo-biological world and social behaviour, hence applicable to governance appropriately modified. The microbiome is a collective term for microbiomes that exist everywhere including “dead” planets. Well, one may take this a bit sceptically as the author cannot commit. But one doesn’t have to go that far when the study is on human microbiome. The fact is that humans need microbes. Do they need humans? Well, not necessary. This is a catch that leads to take them seriously as they have been evolving with humans for the last 6 million or so years.⁸ Therefore, it can be said that microbes too need human body ecosystem for survival to support human existence in return. In a different perspective, human microbiomes do not need human ecosystems unless humans want to evolve further in a healthy survival mode. The fact that microbes were here much before humans

⁸Kumar, A. and Chordia, N. (2017). “Role of Microbes in Human Health”. Applied microbiology: open access 3:131. Doi: 10.4172/2471-9315.100013. <https://www.longdom.org/open-access/role-of-microbes-in-human-health-2471-9315-1000131.pdf>. Accessed 12 January 2020.

and others prior to human life forms also points out to the fact that microbes do not need them for existence. Simply put life formed in all these simple complexification in a progressive manner under acceptable circumstances of energy open, and stored as matter. Today, there is complex and mutual relationship between humans and their microbes. It is also applicable to other life forms and their supporting microbes.

Human microbes exist in different parts of human body according to their characteristics. They are based wherever they are on purpose. There is a kind of reciprocal adaptation where they exist in and on human body. The biomic balance with the human system is delicate. It can be upset by lifestyle and various other factors impacting life systems. Besides, the body-biome interaction can also invite any of the interactive resultants—commensalism, mutualism, amensalism and parasitism.

Though generally studied location specific, human microbiome inhibit almost every part of the body. The identified anatomical niches include the following:

- **Skin Surface (Cutaneous)**

Human skin, as known, is a protective shield in many ways. The skin wraps up the body to its possible minimum size in a compact mode atypical to a cabin baggage in life's flight. People can carry it with them and avoid waiting lines to collect it after the trip at any given time if such trips ever exist. There are no such trips, but one learns from early childhood that skin is a wrapper. Not exactly; it carries a lot of macrobiotic genera of select kinds as bacteria, fungi, mite, viruses and others. The skin is actually barrier to pathogens. Human biome on the skin is residential or transient. They are very much required with respect to the corresponding body for its immune system and other aspects that demand enhanced understanding. There could also be harmful and harmless biomes in the lot.

- **Eyes**

There are small numbers of microbes (bacteria, fungi, etc.) inside the eyelids, the conjunctiva and the cornea. The risk of eye diseases will increase when the microbiome imbalances. Compared to other parts of the body, the ocular microbiome is a relatively small portion. They provide immunity and resistance to the ocular region. The microbiome on the eyelids and eyebrows is considered part of the skin micros.

- **Nose**

Nose and also associated oropharynx are colonised by micros of different varieties including potentially pathogenic ones. The community is established in the first year of birth that will continuously vary throughout life and also based on interindividual variability.

- **Mouth**

Human mouth has everything that can sustain a biome—water, nutrients, climate, etc. The entire bioenvironment remains more or less steady throughout unless the subject is taking medication, drugs, tobacco and other things that are not gut pleasing food. The problem for micros is to remain freely in the oral environment. They hold on to the teeth, gums and oral cavities. If not, the fall is

too steep and deadly unless they are acid resistant. There is a lake of hydrochloric acid down there. The micros comprising anaerobic bacteria and fungi in the mouth are checked by oral defence system. The micros balance pathogens from getting down under. The constituent parts include saliva and oral mucosa. Saliva supports digestive system as well as cleaning the teeth. Oral mucosa is the protective lining in the mouth.

- **Throat**

Throat comprises three parts: the nasopharynx, the oropharynx and the laryngopharynx. The human pharyngeal microbiome is considered playing protective roles in respiratory tract problems. Studies have demonstrated the pharyngeal microbiome comprises an abundance of bacterial species that interacts with the local epithelial and immune cells forming a unique micro-ecological system.

- **Lungs (Pulmonary)**

Lungs are constantly surveyed by the immune system. Besides, the nutrients are highly limited. That makes it generally inhospitable to microbes. Lungs are healthy when they breathe well. But bacteria that get into the lungs along with dust and smoke can make them ill and attract pathogens that can harm it. The microbiome of the lungs has limited microbial biomass relative to other anatomical niches. Yet the biome in the lungs displays considerable diversity. The effect and impact of the biome are poorly understood. The complex interactions between the host, pathogen and resident microbiota in the lung will hold the key for lung diseases especially chronic ones.

- **Biliary Tract**

The biliary tract is normally sterile. Bile is produced in the liver. The biota in the tract therefore is meant for protecting the tract by exogenous pathogenic microbes forming a functional layer. Studies are in progress to establish their potential relations with bile-related disorders.

- **Mammary Glands**

Only females have mammary glands capable of producing milk on childbirth. The human milk microbiome includes the bacteria present in the human milk. The bacteria constitute the human milk microbiome (hMM).

- **Gastrointestinal Tract**

There are detailed studies on microbial populations of human intestinal tract and their relationship to specific diseases. The tract comes with microbiome by birth, though it will make a difference based on the delivery—vaginal or surgical. The former is preferred. It makes the micros comparable with those of the mother. The detour and the time spent along the way do the baby good. It will carry less pathogenic microbes. The microbiome changes in composition in relation to the diet of the individual. Humans nourish their guts externally with probiotic supplement either in food form or prepared for oral admission. More than a thousand different species of bacteria belonging to major phyla (Bacteroidetes and Firmicutes) may reside in the tract along with other biota—archaea, fungi, protist and viruses. Healthy humans have a far higher concentration of bacteria in their guts than in other organs and body parts.

- **Uterus**

A variety of microorganisms inhabit the uterus. The uterus and its tissues are not sterile. The reproductive tract at the uterus end is different from the vaginal and gastrointestinal tract. The uterine microbiome is considered commensal and non-pathogenic comprising bacteria, viruses, yeasts and fungi.

- **Placenta**

Placental tissue carries commensal, non-pathogenic bacterial species and genera. The evidences could be controversial; hence, care is required while examining the placental biome. In another finding, researchers consider human placenta may not have microbiome after all but may contain potential pathogens.

- **Urinary Tract**

Studies have shown that urinary system carries resident microbes of different genera and species, though it is not clear how they react pathologically and what is their relationship.⁹ It is the area where adult humans experience frequent bacterial infection. The biota is believed to contain colonisation of uropathogens. Urinary system comprises kidneys, ureters, bladder and urethra together as urinary track extendable to genital anatomical sites.

- **Vagina**

The genera and species of microbiota in the vagina are critical against infections of the vagina. The micros suppress pathogens. Variations will be there during menstrual process. The vaginal flora is widely influenced by the differences between the women in ethnic differences of all kinds (see definition of ethnicity in the study) including age. Sexual intercourse, condom use and antibiotics¹⁰ can influence the levels of healthy microbes. The flora comprises generally bacteria and fungi. Bacterial vaginosis is the most common vaginal condition and is distantly characterised as the disruption of the equilibrium of the “normal” vaginal microbiota.

- **Ovarian Follicles**

Ovarian follicle is a small, fluid-filled sac in the ovary. It contains one immature egg. There are thousands of follicles in the ovaries. It is the basic unit of female reproductive biology and contains a single oocyte, an immature ovum or egg cell. Ovarian follicles are considered to have active biome though they require more clarity regarding their nature—whether colonised or contaminated. Some authors suggest that the microorganisms could be designated as colonised or as contaminant by means of comparing the bacterial species present in the

⁹Grasin, D. A. (Ed.), (2020). Neugent, M.L., Hulyalkar, N.V., Nguyen, V. H., Zimmern, P. E., De, N. J. “Advances in Understanding the Human Urinary Microbiome and Its Potential Role in Urinary Tract Infection”. DOI: 10.1128/mBio.00218-20. Nisco <https://mbio.asm.org/content/11/2/e00218-20>. Accessed 1 January 2020.

¹⁰Antibiotic is a drug used against bacterial infections. It has no effect on other infections. The first antibiotic was penicillin (1928). In the early days, the antibiotic was derived from a microorganism on how they controlled another. There are synthetically produced antibiotics now.

samples to that found on the surface. Accordingly unique species found in the follicles may be considered as colonised microbes.¹¹

- **Seminal Fluid**

Seminal fluid (semen) contains spermatozoa secreted by gonads and other reproductive male or hermaphroditic organs that can fertilise the female ovum. Seminal fluid is basic and carries carbohydrates. It has the environment for seminal fluid microbiome (SFM). The microbiome can influence not only the child but also future generations (transgeneration).

There can be many unseen biomic niches in human body. All the four symbiotically interactive matrices—commensal, amensal, mutualistic and parasitic—play important roles in the relationship of the human biome with the body. It will give a hint that human microbiome carries life along with other forces. But it can also knock down the body with pathogens. But the “how and when” of it will need more clarity by research and continuous perusal. Frankly, the author doesn’t know. What’s known and believed is that the human microbiome has never before imagined designated roles in control of vital homeostatic as well as homeodynamic¹² mechanisms in the body. Human microbiome may hold the stasis of human internal environment by balancing its rhythm perhaps through its microbiome like the planet cools itself under the biomes of the living systems in it. The governments have serious roles to play in aligning human microbiome security with other elements for governance for this reason.

The difference between the microbiome and the genome of the human body is that the dynamics of the former constantly changes whereas the latter relatively remains more or less constant in a lifetime.¹³ The changes in the microbiome are faster relative to the lifespan of the host body. It changes along the human development, as mentioned earlier, in the utero. There are various other factors that support the change. Some of the identified factors are environmental, the diet of the host body, health issues, medicinal use, etc., the biotic changes maintain the homeostasis which in turn contributes to maintaining the immune system of the body.

¹¹Fransasiak, J. M., and Scott, R. T. Jr. “Reproductive tract microbiome in assisted reproductive technologies”. [https://www.fertstert.org/article/S0015-0282\(15\)02019-1/pdf](https://www.fertstert.org/article/S0015-0282(15)02019-1/pdf). Accessed 22 May 2020.

¹²Explain stasis and the two words with the root in homeo. Homeodynamic is about movement including growth. Humans move all the time every minute in terms of growth that is also to be seen. It should also give larger coverage in health security about micros and their static and dynamic words as two words within the group balancing—homeostasis. That means homeostasis is two—homeostatic and homeodynamic. The latter should not be mistaken for homodynamic.

¹³The term relative is important here. It is relative as the genome change is not “visible” in a lifetime.

24.4 Players and Stakeholders

In all respects, the residents of the microbiomic terrain (human microbiota) have to be those adaptable to the conditions of various habitats of the human body to live and function in any of the symbiotic fashion, humanly beneficial or otherwise. The relationship could be commensalistic, amensalistic, mutualistic or parasitic. This residential adaptation of microbiome would have been carried forward millions of years through various life forms or life generating processes that continued in spite of other temporal changes by energy transfer in and on the planet. Or would have gained by associated energy-mass transfer till life sprouted on the planet. Thereafter the members of the microbiome shifted by various means of multiplication—binary fission, transformation, transduction or conjugation, to the animal habitat as if specially formatted and waiting for them to progress symbiotically in a kind of love-hate relationship. Human body is the last new world (though not probably the last frontier) for the biomic micros, constantly edging to the future. More than individual micros, the biome babies habit non-randomly in groups or assemblages, as understood. They do it non-randomly. It also doesn't seem to be orderly, perhaps unable to point out by research so far. Scientists have observed various abnormalities in several disease states.

The definition of microbiome gives a hint of the players and stakeholders of the human microbiome world. The microbiome is the collective genomes of all the microbes in the assemblage. Randomly they comprise prokaryotic microbes, eukaryotic microbes and viruses. Nearly 1000 species are expected to exist in human microbiota.

Prokaryotic microbes are unicellular without any membrane-bound organelle. Like a nut without kernel. In rare cases, they are also multicellular. They are in two domains—the commonly well-branded and widely known bacteria and the lesser celebrity archaea. The eukaryotic cell is a predecessor before something filled it—the nucleus. They belong to the kingdom of Prokaryota (also more exotically Monera) the most ancient and thereby primitive forms of life and the origin of it all. The DNA is yet to organise into chromosomes, like a production line before packing shop or the pick in a shopper's cart in the supermarket. Well, something like that.

Prokaryotes are the smallest independent life forms. It also shows that prokaryotes must be the first life cells. Among them bacteria has already acquired, as mentioned, a kind of celebrity status to the extent for the uninitiated a microbe is a bacteria. Others would have objected to it, but for their hapless position to bargain collectively. This could probably be a wrong statement because they are also equally powerful according to this study. All of them, the biome babies, can turn around human life, good or bad. Otherwise they wouldn't have entered a study of this kind.

There is a variety of bacteria of assorted shapes and lengths in different species. More will enter when identified. Others, the archaea, are quite diverse though resembles bacteria. Some of the archaea can bear extreme temperature, whereas there are others that can withstand extreme cold (thermophile). There are masters

who can spend the whole life swimming in acid pool (that was never serious about pH) (acidophile), many others equally super in extreme salinity (halophile). Some of them love methane (methanogen), and they get them plenty in swamps or animal guts if they like a candle light dinner inside. So, it is a matter of “tell me the extreme, I will get you one” for the prokaryote head hunters in the office.

Prokaryotes are a major source of enzymes that work under extreme conditions—temperature, pressure, salinity, acidic, alkaline, etc. They have amazing survival mechanisms by default in their genome.

Prokaryotes are believed to have been evolved 3.5 billion years ago (Precambrian period) after passing through long phases of evolution. They were the first to evolve as of information today.

Eukaryotic microbes belong to the domain Eukaryota or Eukarya. They have cells with a nucleus enclosed in a membrane. They are either unicellular or multicellular. From a unicellular microbe to a giant elephant, whale or a tree, the forms are eukaryotic. They include animals (Animalia), plants (Plantae), fungus (Fungi) and others that do not belong to any of the three (Protista). The clear definition for Eukaryote is any life form with a distinct nucleus. The nucleus will carry the chromosomes that carry the heritable information.

Eukaryotes evolved much later, around 1.7 billion years. Life, but for individual lives, as a theme of the living planet, was never in a hurry to establish itself. This is also one of the reasons why looking life and its situation of existence in reverse is important. Besides clarity and better perception, the reverse analysis (driving forward looking the time spent so far in the reverse) makes the result as if not related but occurred in the matter-energy cornucopia. Not something deliberate. This can be seen and understood better with the study of the living micros. This is an interesting find. Individual lives do not seem to be a yardstick for assessing the longer dimension of life in any form of living things.

One of the advantages of human microbiome in governance will be just this—understanding human lives in a different perspective that could turn around governance into a more positive exercise. This is the task for the governments and its agencies and bureaucrats. For this, they would need the support of researchers and investigators.

In the general melee of the microbiomes, the names to count are of both prokaryotes and eukaryotes that include bacteria, bacteriophage, archaea, fungi, protozoa, simple algae and viruses. They exist either as friendly neighbours or damaging parasites but cannot be avoided. Hence making the best use of them is the key to survival and mutual existence. That is where the governments have to step in a human system and align with national security maximisation for human well-being. Brief descriptions of the players of the microbiomic world where the humans are the stakeholders are given below.

- **Bacteria**

Bacteria are the oldest life forms. They are unicellular prokaryotic microorganisms. They have different overall shapes—spheres, rods, comma, corkscrew and spirals. They are present in almost all habitats. The number and biomass of

bacterial cells on earth will exceed that of all the plants and animals many times. Scientists estimate about 5×10^{30} bacteria in 1.5×10^6 species. There are ten times more bacterial cells than human cells in human body. A small percent of bacteria are pathogenic. But that much is sufficient to shake up the health systems and fads to put the world in the sick bed and graves unless careful.

- **Archaea**

Archaea are prokaryotes. Their structure is similar to bacteria. Earlier, they were classified as bacteria but changed when found that there were substantial differences between the two. Though similar in structure, they are built from different chemical compounds. They are obligate anaerobes. Though not strictly pathogenic, archaea has the potential to cause diseases.

- **Protozoa**

Protozoa is similar to bacteria, unicellular but larger. They are eukaryotes. Protozoa eats bacteria as a food source. Some of them are parasites. The present-day term for protozoa is protist and belongs to the kingdom Protista. There about 50,000 species in Protista.

- **Fungus**

A fungus is a eukaryotic organism—yeasts, moulds and mushrooms. Initially fungi were considered as plants, but further research showed they were neither plants nor animals. They belong to a separate kingdom—fungi.

- **Algae**

Algae are a group of microorganisms. They are oxygenic, phototrophic and eukaryotic. Algae have a nucleus, exist as microscopic cells and generate oxygen through photosynthesis. The term is reserved now for eukaryotic organisms. Algae also get energy through photosynthesis. They are neither animals nor plants nor fungi. This study does not consider algae as a human microbiome. But there are research studies that highlight certain algae can improve gastrointestinal health.

- **Viruses**

Viruses are everywhere; they are non-cellular “things”¹⁴ that cannot reproduce itself. They are mentioned as “things” here for they challenge the concept of life as known today. But they are vital for life. There lies the catch. The virus will have an RNA (ribonucleic acid) or DNA (deoxyribonucleic acid) as their genetic material. That makes them a kind of zombies that dance with life (take here). The exotica of the dance changes life (until humans learn deeper). On the question of life, there was never another one “thing” that caused so many ripples in human thinking and still remained where they were. So, let it be here also except that one should know virus exists and it is much more than a “thing” and is involved with life on the planet more than life itself.

Once inside a susceptible cell—there is plenty that yield—the zombie becomes active and orders the cell to produce more of its kind—viruses. The RNA or DNA in the virus can encode proteins—presto! The job is done. Of

¹⁴“Things” is a term used for this study.

course, it also depends upon the virulence (something like clout when one talks about influential people) of the virus. Scientists know a lot about viruses today through their studies on bacterial, plant and animal viruses. Still there is a long way to go even though they consider viruses as fundamental players in the history of life. So, the collective opinions the scientists held once on viruses have changed into specialised findings. They place viruses in a kind of netherlife, neither dead nor live—somewhere in between, a quantum state of life. But not exactly in the incompatible state of the Schrödinger's cat.

Another question that comes is where the study of virus exists with respect to chemistry and biology. Is it in between? For some scientists, they are boxes of chemicals, and for others, they live on borrowed life.¹⁵ The in-between theory of the zombieland holds good for framing their existence in national security studies for the time being. It originates from the recognition that they are vital for life.

Interestingly, all those micros are harmless, perennially around whether other life forms like it or not and therefore must be extremely vital for life as they created life or helped in its formation and evolution. There may be many more around and to come from various sources. That makes microbiome a unique and specific terrain and microbiomic security a separate element.

The microbiota wins from the point of view of life as it inkblots life into time. Individual life is not the point of attention. The life that fits to live-mutate-live (LML) will be energised by the microbiota, and those that are unfit for the LML will vanish as death is necessary for life to continue (health security). Microbiomic security thereby becomes a critical field in governance. But the humans have a lot to know about it. The knowledge perhaps will change the overall perception life itself. The roles and scripts of microbiota will exemplify this statement.

24.5 Role and Script: Microbiota

The role of microbiota is to support life's process. The microbiome constantly changes with the environment and makes the body to adjust with. The primary function as understood is to maintain the homeostasis with the immune system. In this process, the microbiota performs various functions scripted appropriately to the designated roles. The functions of human microbiota are:

- **Displacing pathogens.** The microbiota edges pathogens from colonising the body by competing for attachment sites or for essential nutrients. This has been demonstrated in all the body niches where they habitat especially in the mouth, the gastrointestinal tract, the skin and the vaginal epithelium. This is known as microbial antagonism by which normal microbiota prevents the overgrowth of

¹⁵ Villarreal, L. P. "Are viruses real?" (200). <https://www.scientificamerican.com/article/are-viruses-alive-2004/>. Accessed 9 July 2020.

pathogenic ones. Besides competing for space, they inhibit the harmful microbiota by producing bacteriocins which, lower pH inhibiting pathogen growth, stimulate and shape immune system. They are proteinaceous or peptidic toxins produced by bacteria. This inhibits closely related bacterial strain. Bacteriocins are latent alternatives to conventional antibiotics. They are peptides with high potency and low toxicity that can be bioengineered in suit by probiotics. This is an area where governments can engage to identify viable alternative to antibiotics. This is especially so in handling cases where bacteria is resistant to antibiotics.

- **Preventing disease.** Disease prevention is beyond the singular task of uprooting pathogens by denying space as if in a musical chair. Disease is a disorder that can be defined as a medical condition, not attributable to an injury as the immediate cause, and diagnostically identifiable through specific symptoms and signs. The biotic role is to prevent disease by supporting the immune system balance. Microbiome composition in healthy bodies will give a clue on the requirement of biota to prevent disease. Presently, it is known that microbial imbalance, sometimes termed “dysbiosis”, may lead to the cause and effect study. How the microbiota handles the disease prevention issues is under serious study on diseases related to paediatrics, inflammatory bowel disease (IBD), other bowel syndromes, necrotising enterocolitis (NEC), atopic diseases (eczema, asthma, rhinitis, allergies, etc.), type 1 diabetes, autistic spectrum disorder (ASD), etc. All these can turn microbiota as a therapeutic tool in the future. The objective is to understand the future potential of microbiota in health security. This involves elimination of select microbiota, probiotics, probiotics (enhancing bacteria), microbiota transplantation, etc.
- **Metabolism.** The metabolic process is creating nutrients for host cells. Air, water and food are the three vital elements of sustenance in the triad of life as one knows today. Food generation for host cells from what one eats needs the microbes. Metabolism is some of the chemical activities in a living organism. Digestion of food, its breakdown and transportation of energy substances by breaking down and compounding molecules between cells are all included in metabolism. That indicates biota is critical to life like water and air. Metabolic activities are two types: catabolism in which energy is released by breaking down of molecules and anabolism in which energy is consumed by compounding them. Microbes activate and support and boost metabolism.
- **Synthesise vitamins.** This includes synthesis of B vitamins B12, thiamine and riboflavin and vitamin K needed for blood coagulation.
- **Regulate immune system.** The microbiota induces protective responses to pathogens and the maintenance of regulatory pathways involved in the maintenance of tolerance to innocuous antigens. Immune system will function well if microbiotas support it. This is especially so with gut microbiotas.
- **Detoxify carcinogens.** The role of microbiomes in detoxifying carcinogens is still under study. Cancer susceptibility and progressions are considered to be the outcome of the interaction of gene with environment. Many studies demonstrate that microbiota can increase or decrease cancer susceptibility and progression by

diverse mechanisms such as by modulating inflammation, influencing the genomic stability of host cells and producing metabolites that function as histone deacetylase inhibitors to epigenetically regulate host gene expression.¹⁶

- **Stimulate renewal of cells in the gut lining.** Microbiotas in the intestines are gut keepers of sorts engaged in renewal of cells as necessary in a healthy environment.
- **Promote healthy skin.** Microbiotas over the human skin are engaged in keeping the skin healthy all the time.
- **Decrease inflammation.** Microbiotas maintain correct acidity in the guts and thereby prevent inflammation.
- **Control blood pressure.** Gut microbiotas can also influence the state of immunity and inflammation, cell metabolism and proliferation that may eventually affect blood pressure.
- **Regulate insulin production.** The gut microbiome regulates insulin production especially in those who experience obesity-related comorbidities. This is seemingly so especially in PWS¹⁷ patients when their cells stop responding to insulin and cause an excess of sugar in the body.
- **Maintain tissue integrity.** Implantations and injuries cause tissue trauma evoking inflammation, delayed healing, etc. This involves cell-biomaterial interactions. Tissue integrity allows wound healing which otherwise will be colonised by pathogens.
- **Housekeeping to maintain cell function.** Regular housekeeping is essential for all cells to maintain basic cellular functions. It is carried out by the constitutive genes. In this process, there are many small proteins of the human microbiome that may perform diverse functions on which the studies are on.¹⁸
- **Influence mental health.** Neurologists are aware of the connection between the brain and guts. This means the gut resident microbiotas can influence everything from stress to pleasure and enjoyment. It is known that gut bacteria influence serotonin and dopamine production that leads to the feeling of happiness. Good biota in the guts, researchers found, improves depression.

¹⁶Goodrich, J. K., Davenport, E. R., Clark, A.G., and Ley, R.E. "The relationship between the human genome and microbiome comes into view". *Annu Rev Genet.* 2017 November 27; 51: 413–433. doi:10.1146/annurev-genet-110711-155532. Accessed 16 January 2019.

¹⁷Praeder-Willi syndrome. It is a kind of genetic disorder.

- **Protects host body from toxins.** Bifidobacteria¹⁹ keeps toxins from passing through intestinal walls into the bloodstream.
- **Addresses obesity.** A study in 2013 found that good gut bacteria can address obesity.²⁰

The roles and script of microbiotas in human health are still unknown. Serious research is progressing. Their significance in human health is still debated. While some experts consider microbial density is critical to human health, there are others who consider the types of microorganisms to be of greater importance. However, these and other factors such as microbial synergy, the host immune response and the quality of tissue must be considered collectively in health studies interactive with microbiome.

24.6 Microbiome as Health Guard

Microbiome is not only a life inducer in the planet but also the prime life sustainer along with air and water. Life originated from the triad of air, water and microbiome. Whatever the humans may not know about microbiome, there is no doubt among scientists and bio soothsayers that microbiome, especially the leader of all biota, the bacteria (leader, because humans know a lot about them by now) is not only good but also vital for human health. This makes the microbiome some sort of health guard for the host, something similar to a missile defence system. No, not exactly. Interestingly, the threat of disease cannot be brought under the threat matrix cube explained earlier (Chap. 4). Hence, a preventive shield or guard cannot be the right term to use. But, in the absence of a semantic difficulty, it may be taken as a health guard. Disease is a disorder that is felt (not struck) when immune system becomes insufficient. In the conglomeration of microbes, genome, host condition and above all the melee caused by the system as a whole, the host feels the disorderly order in the system—that is what happens. All factors together handle it.

It is already mentioned that microbiomes are necessary to detoxify the body of carcinogens, help in the renewal of linings in the guts, etc. The microbiome may weigh as much as about 2.3 kg in a human on the average. The bacteria in the microbiome help in digestion, regulate immune system, protect against pathogens that cause disease and produce vitamins needed for blood coagulation. The biota, perhaps, are the best bet for maintaining health. The microbiomes are found essential for growth, resistance and sustenance of humans. The bacteria living on and inside the humans are not invaders, but beneficial and responsible life associates.

¹⁹Bifidobacteria are also called probiotics that normally live in the intestines and stomach. They help in digestion and staving off harmful bacteria. They belong to a genus of gram-positive, nonmotile, often branched anaerobic bacteria. They inhabit gastrointestinal tract, vagina and mouth.

²⁰Quigley E. M. (2013). Gut bacteria in health and disease. *Gastroenterology & hepatology*, 9(9), 560–569.

Autoimmune diseases such as diabetes, rheumatoid arthritis, muscular dystrophy, multiple sclerosis and fibromyalgia are associated with dysfunction in the microbiomes. Disease-causing microbes accumulate over time, changing gene activity and metabolic processes and resulting in an abnormal immune response against substances and tissues normally present in the body. Autoimmune diseases appear to be passed in families not by DNA inheritance but by inheriting the family's microbiome. There is more to know about the fast expanding subject.

Human health care through microbiomes recommends personal diets, probiotics, prebiotics, microbial-based interventions, vaginal macrobiotics for healthy vaginal ecosystem, faecal microbiota transplantation (FMT) and so on. But practitioners and researchers also warn about adverse effects of do-it-yourself practices and warn against microbiome-based interventions without analysing the risks involved.

Human health and its relationship with microbiome have created pharmacobiomics interlinking with pharmacogenetics (Chap. 16). It is the study of how the exclusive human biome helps to design exclusive drugs to people by studying their pharmacogenetical aspects. Pharmacogenetics responds differently to drug therapy based upon their genetic makeup or genes. Diet, overall health and environment also have significant influence on medication response. More studies will be required on pharmacobiomics to understand the nature and prospectus of the subject seriously, hence a matter of governance.

24.7 Human Microbiome Project

Human microbiome project (HMP) was a worldwide research initiative to map human microbiome which opened up a new chapter in the study of microbiotas that sustain human life system, especially by studying human health and disease chains. The objective of the HMP was to examine the uncharted microbiota. The HMP was sponsored by the National Human Genome Research Institute (NHGRI) of the United States of America. The institute was part of the National Institute of Health (NIH).

The primary assumption behind the NHP was the consideration that humans are “supraorganisms” with human as well as non-human cells. The project was an extension of the Human Genome Project (HGP). The question in this study is whether the world should consider microbiomic study as part of the genomic studies or separate from it. This study recommends separating them in a mutually inclusive manner in separate platforms. The reason is that while one is internal (gene) to the human body, the other is external (microbiota) to it even inside, though highly interactive in a symbiotic mode, as is known lately. The external still survives when the internal passes on. The symbiotic relationships of living things are natural, but the life forms still remain separate from each other similar to the hermit crab and the sea anemone relationship. This will support the argument of microbiome as a separate element as well as a new terrain for governance. They are highly interactive and fit well within the basic conditions of identified national security elements.

The HMP, however, was looking at the research as a metagenome characterisation. That is combining the microbiome genes with the human genome. The sampled body areas for the project were external as well as internal to the human body: skin, mouth, nose, colon and vagina. Besides understanding how microbiome can influence human health, the researchers are also able to identify previously unknown biotas. The project findings may lead to new understandings in health science and appreciating the advantage of growing more health supporting biotas and eliminating pathogenic ones. Scientists need to find answers to many questions on the subject. The answers will guide governments in decision-making to maximise microbiomic security. Some of the studies as part of HMP found that there were more than 8 million unique genes associated with various human microbiomes. That means the genetic contribution of microbiome to each human is much more than their own genes.²¹

24.8 Yuck Factor

The yuck factor in humans is an interesting behavioural aspect—repugnance or abhorrence towards something. The study of microbiomes gives an opportunity to mention about the yuck factor. It is there in the opening quote itself. It is a behaviour that is not seen in other life forms. If they carry such behaviour, it could be used to repulse the unwanted among them. Yuck factor means something that induces a feeling of repugnance, revulsion or disgust in people. Even a casual mention of it can cause repugnant wisdom. It is an “appeal to disgust” based on a conditioned belief causing an intuitive negative response to something that could be an idea, concept or practice for the intrinsically harmful or evil. An abhorrent situation causes the yuck factor for the person conditioned by it. It could be generated by an aspect of an idea, action, situation, etc. Though outwardly harmless, yuck factor can interfere with many things in life. It is already there in religious belief systems, hate generators and various areas of ethnic security matters.

The latest is that the yuck factor can play havoc when suggestions come from biomic researchers on the therapeutic or medicinal values of biomes. The human health concerns may go through the yuck factor of abhorrence once the trials are accepted. There are many stories of people who are obsessed with cleanliness. But such people may be making grave mistakes of killing themselves in the belief they are becoming healthy by keeping away from the germs. Sanitisers and commercial germ killers and even soaps and exotically branded body washes may be banned like plastic one day by governments and they may be replaced by the “yucketty-yuck” microbiomic sprays and ingestions and body washes in a shift from repulsion to forced attraction. That is when a bath in milk Cleopatra or any commercially produced microbial (even foecal) shampoo will be preferable for that glow on the

²¹ <https://www.fiosgenomics.com/microbiome-vs-microbiota/>. Accessed 31 March 2020.

skin. Biomic studies in health may make people who are in dire straits with respect to health may have to accept the repulsive attractively in the future.

Repulsive behaviour is not a disorder like obsessive compulsive disorder (OCD). It is a kind of conditioning. De-conditioning by self can change a person from such behaviours. Hence the yuck factor needs not be a serious matter when the individual decides to break away from it. This will be required in biomic treatments for health concerns. The already in treatment technique that carries yuck factor is foecal microbiota transplant (FMT) in curing *Clostridium difficile* infection. It is the stool treatment. The stool from a healthy donor is transplanted to someone to treat a bad gastrointestinal condition. It has been found promising treatment in gastrointestinal disorders, especially ulcerative colitis. The “yuck factor” needs not be a cause of worry in biomic drug applications including what the companies call the “poop pills” related to FMT. Many biomic companies will be involved in harnessing bacteria and other microbiota to develop new drugs. The yuck factor will not deter humans when their health is at stake.

24.9 Maintaining Human Microbiome

Maintaining a good human microbiome under safe and ethical considerations is the underlying principle of the microbiomic security. Governments can incorporate it in national security governance as a common element specific to human well-being. Maintaining the health of human microbiome, in this aspect, is. The findings of microbiomic research will change the way humans live. The study will extend to plants and animals. It is important for individuals to understand the need to maintain their microbiome healthy for various reasons including eliminating the unwanted ones. But there is a general tendency to treat all micros as unwanted germs. Fear of germs has to change to fear of toxins. The objective is not to kill the germs but expurge toxins. Microbes are as necessary for life as air and water, well, almost. At least humans are aware now that germs save. There are many advises given by those dealing with the study of microbiome. Many recommend prebiotics and probiotics for good gut feeling (Box 24.3).

Box 24.3: Probiotics and Prebiotics: What Is the Difference?

One easy explanation is that probiotics are beneficial bacteria, and prebiotics are food for them. Probiotics are found in certain foods and supplements. Prebiotics are certain plant fibres that humans cannot digest but help in balancing gut biota. They travel all along the digestive system. The beneficial bacteria consume them. In fact the prebiotics fibres in the food feed the good biota, mainly bacteria. Balancing them in the diet will balance them and keep the gut healthy. Prebiotics support probiotics that support healthy metabolism. Simply put eating the right food for the individual can make all the difference.

Researchers advise that one should make sure that probiotics and prebiotics are effective before taking them by consulting experts. Probiotics are living organisms whereas prebiotics are not. They are plant fibres.

24.10 Managing Dysbiosis

“Dysbiosis” is a functional and qualitative perturbation of microbiome in human body. Dysbiosis increases risk to certain diseases as the change can increase the harmful biota. The lack of essential bacteria can cause a complete revision of the bacterial ecosystem. The solution for that is reintroduction of healthy equilibrium.

The opposite of dysbiosis is eubiosis. Eubiosis is total symbiosis between the human body and its specific microbiota. It is a subject that has to be handled under effective microbiomic security governance. Various aspects related to health security, ethics, rule of law, etc. are involved in handling these issues.

24.11 Counting Human Microbiome

Human microbiotas are separate from human cells that accommodate them. There are more microbial cells on human body than human cells. Some say that their ratio is 10:1, but some are attempting to correct it to the ratio of 1:1 lately. That doesn't matter. Perhaps microbes may have the last laugh one day against the arrogant human. But for now the counting lacks scientific evidence that is universally acceptable.

24.12 Terrain Relativeness: Microbiome

“Microbes preceded life and thereafter reached wherever there is life” is a statement that may need more clarification to appreciate. It is true that the geophysical terrains land, ocean and air are the habitats of microbes as they provide excellent environmental conditions for their habitability. Now the scientists are also able to identify the presence of microbes in space. They located them colonies in the international space station (ISS)²² like a ship captain suddenly comes across stowaways on board out at sea. But one doesn't know they boarded the flight from planet earth, the Gaia that loops all life in it, or encountered in space from where they perhaps originally

²²Shah, S. “The ISS is crawling with nasty bacteria”. <https://www.engadget.com/2019-04-08-iss-bacteria-nasa.html>. 10 July 2020.

boarded the planet. It shows there is life where microbiomes exist or it could be where there is life there will be microbiome. They seem inseparably mutual. That means they can also be damaging. Space scientists confirm it. They have located disease-inducing bacteria and fungi in the international space station. These are natural microbes transported by humans on various places, the land and ocean. Yes, obviously they can cause diseases inside a space station as if on earth which will require an ENT (ear, nose and throat) or a GI (gastrointestinal) specialist. This can impact the health of the astronauts while on flight.

Locating bacteria in ISS shows not even hermetically sealed spaces can be free from microbes, and they could be extreme life forms in survival. If that is so, the study on them needs to be as aggressive as them. Besides being hermetically sealed closed system, the space station is subjected to microgravity, radiation, elevated carbon dioxide and recirculation of filtered air.²³ It is considered an “extreme environment”. While this is an area of study that will guide future deep run space travels, it also points out that all the physical terrains are linked by microbiomic security aspects for habitation. This find is important for governance by national security. The terrain relativeness of the element is total in national security studies by direct involvement.

24.13 Host Relativeness: Other Life Forms

This chapter mainly speaks about the study of human microbiome. But microbiota is available everywhere in every terrain including human body. The biomic microbes in their habitats are also equally important in governance. The term host is used to the environment of a particular set of microbiota that lives there as a symbiotic habitat supporting agent. This aspect makes the microbes host relative. The human microbiome is relative first to the human’s body as a host and within that framework remains there as a signature microbiome. This biomic signature keeps changing without losing the identity of the individual host signature, initially at a faster rate slowing down towards aging and disability.

Microbes exist in all kinds of habitats or hosts. Primarily they are two: living and non-living. In the living, the familiar entities are humans, animals and plants. Everything else is in the non-living habitats—earthly, aquatic, atmospheric or spatial. Each one of them also has its individual signature like the individual human or a cat in the living format. The presence of the microbiome in a particular habitat also influences the habitat symbiotically. It could be in the soil or on the tabletop keyboard. The microbes are host relative, and their nature too follows the host characteristics.

²³ Filtered through high-efficiency particulate air (HEPA) filters. HEPA is an efficiency standard of air filters.

24.14 Microbiomic Ethics

Twenty-first century is of microbiomic studies, and awareness is made possible by high-throughput biotechnologies. It is also the century of ethics in human governance according to the author for specific reasons. One of them is the abhorrence to war that has been highlighted in the opening quote in Chap. 8, “War is over”. If that is so, microbiome studies though in the initial stages in the new century could be a subject that will move ahead in tandem with associated ethical practices *ab initio*. Well, more or less. It is also important to understand such studies with ethics followed can turn the table for many unethical practices in every walk of life under the umbrella of governance. People will find many such practices, for example, abuses of pharmaceutical industry and associated corrupt practices, health-related plundering from people and governments and so on, may come under the purview of microbiomic ethics in modern times.

The study in microbiomic ethics will be part of the main subject of bioethics which also includes ethics of genomic research and genomic justice (see Chap. 23). Microbiomic research has the potential to change the entire human health scenario drastically—health practices, clinical applications, illness prevention, public health interventions, healthcare practices, social and individual health benefits and a host of affairs of health that will affect national security and, thereby, human well-being. The entire health industry and associated economics will undergo a paradigm change. In this scenario, there can be many resistances to change even if it is confirmed for the better. These resistances have to be seen in the light of newly found microbiomic ethics while proscribing changes without vested interests and taking human considerations to the utmost value. Microbiomic ethics may seek consideration of human body as a habitat with an ecosystem favouring the growth of microorganisms for symbiotic interventions in survival in the quiet for continuance of life. If that is so, the purpose of life turns out to be nothing else but life itself—individual life forms hang on till the designed life breaths. But the life continues. This is where the microbiome assists life. The living human becomes one with the designer microorganism carried by him or her. It is not necessary for the humans to change their conception of self but should know that the self also contains in the world of the individual microbiome, without which self cannot exist. This is the ethical principle behind human microbiome.

The ethical aspect can come in the forethought of how one shares his or her microbiome with others or how one seeks it from others. Is it like sharing or transferring organs? Can there be microbiomic banks in the commercial arena? How will governments regulate such attempts to commercialise microbiomes for not only human health but also for other fields involving animals and plants. How the donor behaviour will be modulated? The world is aware that microbiome is important to human health. This study considers microbiome the third most vital element for life after air and water, provided there is a body. What the world doesn't know yet is “how much”. It will be identified in the process, and the process has to move ethically, especially in a world that is aware and more advanced than before.

Yonghui Ma et al.²⁴ (2018) have certain recommendations on microbiomic ethics in the following areas in relation to human microbiome:

1. **Personal identity.** The personal identity is framed from the disturbing question, “Are we the sapiens that we think we are even if half our cells are not homo sapien cells?” The authors argue that the microbiome coevolved with the human host genome and hence a symbiotic part and not separate as part of the environment.
2. **Risks, safety and privacy.** The authors suggest the research in microbiome should allow certain risk-benefit ratio in such a way that the benefits outweigh the risks.
3. **Informed consent** of the subject in microbiome-based interventions should be made applicable to microbiome research as in other fields of biosciences.
4. **Biobanks.** These are the depositories of microbiota specimens for research. These are valuable health resource. They should be useful ethically to other research organisations for common good.
5. **Commercialisation and hype.** Research findings and development processes can get bogged down by commercialisation and hype by (mis)presentation by media hype that will create excitement and expectations in public that may often prove to be unwarranted and untrue. The industries associated needs to be regulated.
6. **Public health.** The research in microbiome should be solely aimed at public health and common good. This will demand disease surveillance, racking and data collection on disease outbreaks and deaths.

24.15 So, What Is Microbiomic Security?

Microbiomic security, in this study and as of now, is the 16th and final element of national security in the chronological hierarchy. Microbiomic security, “microbiomicsec” in short with the allotted symbol “m_{s2}” is the latest qualifying element of national security in this study and covers only human microbiome for the moment but can include microbiomes of other life forms too once their functional potential in human life and administration is identified and critically understood. The microbiome, especially the human microbiome, is a widely discussed topic at the moment in the bio especially pharma industry. But there hasn’t been any sensational achievement latent in the expectations on human health care and improvement. But the potential of microbiomics as a field of study or human well-being is widely recognised. There are issues for venture capitalists and on matters related to microbiomic ethics and regulations. But they will be temporary in a world that is

²⁴Ma, Y., Chen, H., Lan, C., and Ren. J. (2018). “Help, hope and hype: ethical considerations of human microbiome research and applications. <https://www.ncbi.nlm.nih.gov/pmc/articles/PMC5960465/>. Accessed 1 July 2020.

always engaged in experimenting with the future. Microbiome is a leading edge science.

Human microbiomic security is the only element in the terrain at the moment and most probably for some more time. It is interactive and integrable with all the other terrains and elements.

24.15.1 Microbiomic Security: Definition

Against the background of this study, microbiomic security means “the capability of a nation to effectively understand, appreciate, regulate, communicate and utilise the value of microbiomics for human well-being in a responsible and value based manner within the national and global context by governance, perfectly aligned with the other elements of national security and integrated with all the terrains of national governance”.

24.16 Summation

The microbiome related to life forms is considered a separate terrain in which only the human microbiome is examined for this study as a separate and most recent element of national security. Human microbiome governance has the potential to improve human health, physical and mental wellness that can contribute significantly to productivity and the overall national security maximisation. There is a complex symbiotically connected relationship between humans and their individually dwelling microbiomes and the environment. Research in this field will invite ethical, legal and social implications (ELSI) as in genomic research (Chap. 23). In the controlled ethical environment, the research can achieve the desired results to support the progression and advancement of life under effective governance. Though seemingly similar to genomic studies, there are vast differences between the two. In genomic studies, the life form is not a host, but in biomic studies, the separation in host position is very important to understand even though the relationships are inseparably symbiotic. This makes the difference between the two studies and therefore is the reason to consider as separate terrains for governance. The author suggests that the studies, at least from the point of view of governance, are taken separately in clear and distinguishable manner for maximum result. An interesting concept in human microbiomic security is the foecal microbiota transplantation for therapeutic purposes which though contains the yuck factor in human perception can also lead to abuses. It also runs the risk of becoming a panacea for many health concerns. This coupled with “do-it-yourself” biomic kits as self-treatment salvage can cause concerns for the governments. Therefore, the demands on the governments to regulate human microbiomic governance will only increase in the future.

Another case is caesarean childbirth (C-section) which misses the natural absorption of microbes during passage through in relation to microbiome studies (Box 24.4).

Box 24.4: C-Section and Vaginal Delivery

There are advantages and disadvantages between C-section and normal vaginal delivery. This study is concerned about the child missing the microbiome of the vaginal passage which being the natural process presumably is more beneficial for the child's future health. The concept at the moment remains as a hypothetical appreciation. Direct delivery is often done by medical practitioners when vaginal delivery put the baby and the mother at risk. Some women plan to have a C-section by choice. The better side of child birth is a matter of bioethics as well as medical efficiency.

Human microbiome is the combined genomic information of the biota residing on and in the human body that consists of the collective genomes of commercial, symbiotic and pathogenic microorganisms. It is a living colony of different microbes in various genera and species that the human body harbours in various niches. They are important for life though not constant throughout. The biome changes with life. There are multiple studies on human microbiota and its role in development of disease. The microbiota consisting "germs" or "bugs" were considered toxic for health along the grapevine in human system. People still believe that all bacteria are dangerous to health. Only now the awareness has come among part of the general population that microorganisms are essential for health. It is for the government to understand the true nature and promote microbiomic health supports. But the microbiota is unique for each human. That can be a serious constraint in understanding the common cure for a population through pharmacobiomics procedures.

The microbiomes can be useful if the probacteria or probiomic organisms are balanced with those that are bad. The human microbiome is a mix of both more so the latter as understood. Everything connected with lifestyle and environment can impact on the biomic mix of a human. But it is important to understand in microbiomic governance that they are not terminators and have the potential to become the ultimate preservers of life even though there are bad guys or those who can turn bad that scientists have to research and warn (Box 24.5).

Box 24.5: Micros Turning Bad

It is a supposition that an otherwise health supporting inhabitant micro can turn bad when moved to another habitat, say, to the gut from the mouth, and still survives there. If it is true, it needs caution as it can induce health problems especially among immunocompromised. There are proven issues of marine microorganisms turning predators in a new environment travelling inadvertently through ballast water carried by ships demanding regulations to control it.

25.1 Introduction

When did humans become humans? The question will puzzle the questioned as well as the questioner. It calls for serious verifiable and veritable definitions for the two words that look and sound the same. But, prior to looking at the answer, one may refresh a bit as an aftertaste in this study so far. *Homo erectus* became *Homo sapiens* 200,000 years or so ago. They are called the great apes along with another four—orangutan (*Pongo*), gorilla (*Gorilla*), chimpanzee (*Pan troglodytes*) and bonobo (*Pan paniscus*)—all apes. There would have been quite a few in-betweens, assuming

evolution is a continuum not staccato originations. That doesn't matter, even otherwise in the present context. They are closer to humans as per the line-up though the last two may have some competition in protocol to sit next to a human on a roundtable.¹ Humans are included in their list as the last successful progeny of sorts. The magnificent five, the great primates without great tails and sequentially a bit ahead of their ancestors in intelligence (they can peel bananas better) were quite advanced though cannot be concluded as miracles of evolution.

Nay, humans cannot accept it. They will litigate if called apes, even if it is true. That is where the crux of the problem lies. Finding an identity beyond and above that of the remaining great monkeys is a hard game when the scientific truth is not agreeing the demands of human esteem. It is visible in the use of their intelligence. Human intelligence, if it is a survival tool, is expected to be used by humans in a way other than the ways of their ancestors, even the closest ones, by sheer practice. No, that is not what happens. The hidden primateness² in human nature rules at critical times. Human intelligence is mostly used to replicate the survival tools of their ancestors. Superior intelligence, the survival tool of humans, is used to replicate the jaws, muscles, claws, quills, toxins and other direct survival tools of the antecedent life forms. They are called weapons. They still use stones as a weapon. The difference is that it is called stone pelting. There is a kind of devolution or going back while surging—the back slip and forward move as if on the camel back. The life system is surging in evolution. The momentum of evolution surges forward and backward with the resultant momentum providing the necessary edge ahead. Surging is unlike the inkblot which doesn't move backward. This needs to be examined to conclude whether the evolution of life is surging or unidirectional spreading (blotting). For the time being, it is considered surging but inkblot is used to model the spread for explanation where required under the assumption that the surge backward is negligible and can be accommodated in the model. It is a kind of falsifiability.

In this statement, the central life system is seemingly surging. Imagine an inkblot spread that decides to withdraw a bit after spreading forward, like the simple intelligence testing question of a person climbing a gradient slipping fractionally backward after some climb and asking to find the time to reach the top. Simply put, it seems the life system as a whole evolves forward frequently devolving in the reverse in a surge—little forward and a little backward every time or at odd times. The author is not clear about it. The author believes the year 2020 if studied well may give some clue on the surging evolution. Some aspects of human intellect provided visible (forward) evolution at time. Sometimes it slipped and devolved. Humans evolved a little humanely and a little not so humanely in everything they do. If that is so,

¹Prüfer, K. et.al. "The bonobo genome compared with the chimpanzee and human genomes". *Nature*, 28 June 2012, <https://doi.org/10.1038/nature11128>. <https://www.ncbi.nlm.nih.gov/pmc/articles/PMC3498939/>. Accessed 11 July 2020.

²Of being primate by design.

humans may have to wait a long time before becoming truly humane. Got it? No, sir/ma'am.

The mother of all questions in national security governance posed here in the opening sentence is whether the human system needs such conceptual governance the way explained in this study as a wholesome concept of well-being, and, if so, are they ready for it? In that case, one needs to see whether the humans known as *Homo sapiens* are ready to use their intellect as evolved humans in a forward looking stasis understanding the advantage and benefits of a centralised governance for collective benefits in a nation-based format. The answer is, “No” and perhaps “Never”.³ The human system will always have priorities based on belief systems. Self-centred anxiety out of sheer insecurity compounded by perceived security and various other needs makes a human under governance a variable component in behaviour. Fear, experienced in insecurity, remains the key. National feeling will remain a niche of convenience within the binary polarity of politics and belief systems. A nation will be inferior to the belief system at the same time a comfort platform to talk about sovereignty as a term of convenience. War is used to be an act of convenience to shed the discomfort of conflict thinking (when diplomacy and similar efforts fail, etc.). In the absence of war that is predicted in this study, at least till 2030, by the quote “war is over”, the world may witness conflicts of all kinds, some of them hidden, as human system will have to be in a situation other-than-war if the chances of all-out war are sensibly waning. The problem here is how a warless situation will turn around with respect to conflicts especially since all other activities will continue under the law of invariance. Humans need to clash. They have to kill. That is a built-in requirement. Can a government provide opportunity in the least destructive way?

Humans learnt to stand erect on two feet many years before they even thought of kicking a ball with them. That is when they have to balance on one foot. They can also dance with one foot waiving the other in the air temporarily. But the evolution prefers symmetry. Humans did not become monopods or skiapods. Evolution respects the most powerful force ever known so far and not yet understood completely—gravity, copyrighted by the only science, physics.⁴ Gravity is there in social sciences too. But all these do not matter in governing humans. The question is have they become sapiens?

In this case sapien with respect to this study needs to be defined to avoid semantic dissonance. Sapien, according to the author, is the human form separated from the *Homo sapien* mould as a first-generation intellectually oriented species that stand unequivocally separate from the family of great apes with a dynamic precinct focused on future. Simply put, sapien is the human who understands intellect is

³One of the theories of the author in marketing products is that never wait for the consumer to be ready and asking for your new product. Just put the product in front with certain differentialities; they will lap it up. That is what humans are. That is also about marketing governance. There are reasons behind this theory. Not explained further.

⁴Author's view for this study.

for the well-being of all in the species and limitations are meant to overcome and not restrict. There is more.

The answer to “Have they become humans?” is important to decide on raising the level of humans collectively for which the time is nearing. Raising the level of humans is limited to the extent humans think they are worthy of it. It is required for what this study advocates—national governance towards sapien, not human, well-being. The reason is that humans should be ready or rather reach the minimum level when their well-being can be established based on this study on national security. They should appreciate the meaning of well-being even though experiences may diverge. That is the stage when they turn to sapiens and are ready to accept governance by the ideated concept of national security. The qualification for well-being in human system stasis is when the system is ready to be governed for it. Looking at the human system scenario, mostly there will not come a time when the people will be ready to accept collective well-being under the powerful survival emotions complicated under various factors such as belief systems, binary polarity of politics and religion, ethnic diversity and so on. The system is ready when the members collectively accept the idea of well-being. It is not the same for all within a system. Worst, it could even be contra. Two groups in the same country may have two different expectations of well-being differing from each other based on belief systems making the system vulnerable. Governance can handle them. But there are hurdles. One is violence, the natural human (paradoxically) security blanket. People indulge in violence under insecurity and fear.

The psychology of violence and criminal behaviour of social systems make governance difficult. The criminal devolution of human systems indicates how difficult it is to govern under the principles advocated in this study. But this, the author believes, is the only route to maximise national security by governance. Here the term devolution is used to show the degeneration by a negative tendency—criminal urge for survival. Devolution is the reverse inkblot. It is similar to the dryness that seeps out on a wet beach when the waves retreat. In the case of humans, it is retreat or the tendency for residual long-lasting conflict. That is the time humans become humans. This is the first step before turning to a sapien. That is the time governments have to be taught to govern for well-being. It is this concept that is called national security. National security is in elements that are mutually inclusive. It establishes integrated terrain specificity through governance. But it cannot satisfy people totally because of limitations in governance including perceptual dilemma of people caused by perceived security. They want more. Hence attainment of national security is not possible. It should actually take a load off the government because no government should be compelled to find the ultimate national security objective. Rather they will keep going towards it by maximisation. It is a good choice in a game where there is no requirement to fix a definite target but a target, yes.

Humans have gone through extreme difficult times, much more than other life forms. Criminal and violent history of human system is pathetically shameful.⁵ It is surprising in spite of such shameful history humans are benefitted by the most advanced survival tool—intelligence. Is the survival tool too sharp to carry safely without cutting self? Intelligence is a double-edged sword that if not used carefully can damage self. It can cut both ways. Presently it cuts mostly the negative way. Humans may call it competition without seriously thinking about the negative surge backward. This is not a philosophical or theosophical slang but a defined finding of sorts. The subject of national security as explained in this study is about living a life well, at least to the extent possible. The extent possible is the limit to which humans can be taken by governance by a governmental system. That is the limit to which national security can be maximised.

The history of human system so far shows a miserable past. Under the law of invariance, the same wretched life is assured in the future too for generations to come. The package may change. It also assures a good time for gods, preachers, political gamers and criminals of every variety. People will continue to wade through hellfires and floodwaters all through their existence. The only relief (if it is so) is that an average human life is relatively short even if one doesn't die prematurely. A long life span is nothing compared to the span of life. There was never a moment when humans were comfortable even in the best possible moments in their lives. This is how a human may express about himself or herself in the run for survival in a planet which is absolutely perfect for them to survive. The proof lies in the survival of other life forms without much hang-up. Every other life form is relatively better than the most advanced form of life on the Planet today—*Homo sapiens-sapiens*. Is it because they don't have the need to govern?

The human who became human is called the *Homo sapiens sapiens* as the subsystem of *Homo sapiens*. The human that the *Homo sapiens sapiens* could turn out is the *sapiens* which for the purpose of this study is the sapien human also termed sapien in singular and sapiens in plural. The *Homo sapiens* will never become a sapien completely by sheer genetic advancement as it is not about taxonomical species change. This study doesn't have the time to wait for the next milestone in evolution. The natural frequency of human evolution is frustratingly incalculable in the reverse count by reductive time. Therefore, the date for the sapien human is taken at the twenty-first century. The action is not by evolution but by autosuggestion like a little child feels he is a knight by holding a wooden sword. The only difference is that it is not momentary or quixotic, but in a continuum forward. This study can't wait. This is the time for introducing the concept of national security in governance where the objective is maximising national security for sapien human well-being by governance by sapien humans.

⁵Collin Wilson (1984). *A criminal history of mankind*. Granada. The narrative is just one example of how human system destroys itself in spite of a better survival tool. The author's take here is that humans will have to destroy themselves by default as a balancing force of evolution along with the laws of limitations for survival.

The trendline starts from here. The rest is cultured over it like a raindrop over a micro-dust particle.

25.2 About Trendline

A trendline is a reference line to explain the dynamics of something, a considered concept that is developing or developed with respect to time. Though a trendline can explain the trend of the past events, it is generally used to explain the future. It is easy to arrive at in some cases like the fluctuation of share price or quite cumbersome and difficult while predicting the evolution of a nation. The latter is of interest in the study of national security. But governing is not an easy. That is why governments are restive.

In stock tracings, the trendline can be plotted over highs and lows to assess the share value fluctuations and the trend. It is a single parameter—the price. It is not so with governance or the development in a nation's case. There are multiple parameters. More than plotting the trendline, the difficulty will be in assessing the multiple parameters that are associated with the concept. If the country is able to assess and record NSI for a particular period in time, it will be easy to appreciate the trendline on it. It becomes the single parameter. But calculating the NSI will be complex. The metrics need to be identified and accepted. It needs research. It has to be simplified in its conceptual stasis. If so, the trendlines in national security could be identified around the conceptualised NSI or the latter can be arrived by assessing the trendlines on considered factors that will lead to NSI computation. Both are inclusive. Therefore, the trendlines as well as NSI will keep changing as the perception improves for the better.

In some calculations, such as share price fluctuations, the trendlines become visual representations. They will show on one side the support and on the other the resistance or limitations in the development of the concept in time dimensions such as speed of development, concentrations, stagnations, etc. Trendlines could also be the bounding lines or limiting lines, or simply the track on which a phenomenon or concept develops. As in any case of management or governance, trendlines are meant for making decisions.

Trendlines are drawn in different ways subject to the rules that apply for each. It is done in maths to show the way a graph is growing through various points or in statistics going through the middle by cutting the data in half or other statistical methods. Interesting aspect of a trendline in general is its three different tendencies—positive, negative and null. A null trend is also no trend. Positive trend is when increase in one set of data causes the other set to increase. If opposite, that is when one set increases the other set decreases, then the trend is negative. If one set of data increases and the other data doesn't seem to increase or decrease (no change), then the trend is null. In the elements of national security, there are many such sets. The data can be within an element or across the elements. For example, for most countries, the need for a military is for war preparations especially to defend an

invasion. For many others, the need may be to invade another territory. Yet another may want a powerful military to increase its bargaining power across borders. The acquisition of weapons for warfighting whether in a defensive or offensive posture or holding the prospective aggressor without engaging will cost money among other things. The increased milsec by spending may bring, for example, a decrease in econosec. It shows the trend is negative which advocates it is better to reduce defence budget. But if the war brings more economic assets, then the trend is positive. Here national security is on a positive trend favouring war efforts. This was the principles that many conquerors employed in the past. They expected an increase in economic security. Saddam thought of it when he invaded Kuwait on 2 August 1990. He wanted money to run his country. There are also kickbacks under corrupt practices in military acquisition. It is big money. The trend here becomes complex by mix-up of objectives when the purpose of build-up becomes internal power acquisition in political analogy. The assumption on elemental variations is based on the assumption of zero sleaze in governance. Potential sleaze upsets assumptions and calculations.

But war is not an easy choice for nations nowadays. This shows negative trendlines in milsec for various reasons. One of them is global dissent on war. Such factors can affect many decision-making processes in governance. Here trendline assessments become one of the options available for governments to make decisions. Trendlines are more effective than analysing trade-offs in decision-making, the author believes.

There are many aspects that can affect trendlines in national security and national security governance. National security is a multi-parameter concept. The factors that affect trendlines in national security are people, government, definitions, elements, terrain, strategies, metrics, indexing, system feedbacks, global stasis and a host of others. Trendline analysis for national security, therefore, becomes a complex activity as there are too many parameters to assess. They are not similar to what the traders draw. This area needs further studies. It will be difficult for a government to predict and make decisions the way a trader does in a stock market. As in trade analysis, trendlines in national security should show the direction and speed of national governance in any country. That is provided such trendlines are brought into practice in national governance. There are many aspects to be seen in national security relative to drawing trendlines if taken seriously. The subsequent sections examine some of them.

25.3 Contrasting Perspectives

The traditionally accepted function of a state is power maximisation. But national security concept is not about power maximisation. It is national security maximisation. The caveat that national security is a conceptual entity that is never attainable in its fullest sense contradicts this objective. Though national security is appreciated as a measurable entity, the quantum is not precisely identifiable in the

human surge as the world moves forward in time, the entropy⁶ leading to disorder notwithstanding. It is the process of heading towards NS_{max} that will make governance ideal and acceptable in the best possible way. It is an ocean where a drop really matters, and a drop it will be, when the change is evaluated. A torrential rain will have its beginning with that one vapour molecule that rises from the sea first.

Another block in the lock⁷ is the people to whom national security objective, the well-being, is aimed at. They have to be competent to appreciate and accept it. It is an assumption that they are competent to accept it. People are conditioned by primate behaviour and find it difficult to use their survival tool in an evolved state. A close but narrow observation by the author on homeless people who slept on the footpath in the mega city of Bombay (now Mumbai), also called the maximum city, in 1973, showed that they were not as uncomfortable as what those who had better than the footpath apartments to lounge and sleep in the megacity. The coping behaviour made them get habituated and think positive with pleasures leading to occasional bout of happiness as in the case of anybody else. They were upset only when their spots on the footpath were taken at the critical time. They adjusted themselves to the situation. The problem they might have was when the authorities chased them away from the footpath even if alternate accommodations were given.

In a world where people and their governments consider nuclear bomb as a weapon that can force a potential enemy to halt its advance in the extreme phase of attack, other than a tool to disintegrate a meteor from outer space heading towards the planet, people still devolve in their thought process succumbed to the existential dread. They may not be ready for national security governance. Yes, one of the conditions the author lays down for a human to become a sapien is to accept the nuclear explosive device (NED) not as a weapon against each other but a tool for the collective security of planet and replace the principle of first or second strikes to no strike individually. It means a collective global nuclear doctrine replacing the national doctrines of the possessors. That is why the unitary civilisation is in a worm tunnel with two different ends—the *Homo sapiens* and the evolving sapien human in various stages in between. It is not uniform.

But nothing prevents humans to believe and pretend they are sapiens, a step ahead, that is sufficient for the time being. That is how one can create chance for a positive outcome. Yes, chance can be created even in a test tube.

⁶A term that the physicists identify with disorder. Increase in entropy roughly means increase in disorder in a system. More on it in Chap. 6.

⁷A phrase used to remind the reader that national security is like attempting to open a physical lock where the original key is missing or lost. But it has to be opened with available “whatever it is” keys or mock keys which are not replicas with allowable key relevance. The mock key will experience many blocks that the opener has to overcome before finally succeeds. That is the block-in-the-lock. The original key is the standard that will not face any block-in-the-lock. There are many situations in national governance where the governments will have to open it without original key. Even the duplicate cannot be made without the original. Ability to open it makes the difference.

25.4 Change and Adaptability: Chance Theory Paradigm

Change is a constant companion of evolution. It is a function of time. The changes are large enough for the humans to experience, but never to perceive directly because of the inherent familiarity of adaption to environment. Ideally adaption precedes perception in an infinitesimal time.⁸ Otherwise, it will cause resonance. The counterpoint is that, within adaptability, the capacity to perceive the rate of change in its minutest form lap dissolves into nullity without being noticed. Any deviation in this inbuilt mechanism will affect the human ability to adapt. The humans will find it extremely difficult to adapt to the change-induced environment if they have the ability to perceive the rate of change in the spec of its span. They will miss the motion of life if they perceive the change clearly and when it occurs. That is why the humans wake up to the reality of life at odd times, often far later than the time when the change was first induced—aging, for example. Just like the way one does not perceive the daily growth of a small sapling in the backyard, changes in the quantum of national security are observable only after a lapse of good time, yes, very good time. That's why a government suddenly realises what the predecessors had done in the past was not so fair dinkum and hoots on their follies. Reversals are more perceivable than advances. That is because humans have an uncanny knack to perceive disorder faster than order. It is necessary to act, perhaps. Besides, changes in an orderly system are heavier towards its degradation than its upgradation.

The more the adaptability to life and environment, the less will be the perception of change. It is a paradigm of chance theory in which increased attention on a particular system element makes one lose sight of a corresponding element in a particular fraction of the same system. That is why when everything is seemingly going “right”, disorder suddenly appears as if from nowhere into it. Actually, the disorder thus appeared is not external, but internal to the system. A disorder is not something that is dis-. Even a windfall is a disorder in chance theory.

25.5 Dilemma of National Security Concept

National security is one such concept at macro-level. It is a subject that is widely discussed in varying shades. The world, compared to the relatively forgotten past, is better today with respect to satisfying human needs in spite of the law of invariance. In national security, where and how far one can reach can never be estimated, at least for now. What is known is that even if one reaches the final limit, it will never be known because that is where apparent security merges with perceived security. The difference cannot be made out. Perceived security will make the people believe that they are far below the level in national security. Those who govern should be aware

⁸It happens in every life form as a survival requirement. Only humans perceive mentally. Hence it has to be true for *Homo sapiens-sapiens* too.

of this vital aspect of human existence. While apparent security is the level of national security that is limited by governance, the oft-inflated perceived security is what the human beings will aspire for because of the overarching influence of individual needs. The level of apparent national security should ideally remain constant when the humans advance. It is the effort of governance to achieve apparent national security that will vary with human advancement. Perceived security will undergo major upliftment with the increase in efforts for apparent security. In other words, the government may find it more and more difficult ideally to satisfy people with advancement unless they too advance.

Today, many nations have internally conceptualised national security apparatuses in place for country-specific needs. Most of them vary in their understanding of the principles of national security and its conceptualisation. It was mentioned earlier that the concept of national security found its origin in the United States. The reasons were obvious and natural. It was first mentioned in 1790 at Yale University as a concept that is not all about military and physical security of a nation. In 1947, in the aftermath of the Second World War, the United States established the National Security Council (NSC) within the Executive Office of the president, under the National Security Act (NSA). The function of the Council was to advise the president on domestic, foreign and military policies related to national security. The president of the United States is the chairperson of the Council; other members include the vice president and the secretaries of state and defense. Advisers to the Council are the chairman of the Joint Chiefs of Staff (JCS), the director of the CIA and other officials whom the president may appoint with approval of the Senate. The Council staff is headed by a special assistant for national security affairs, who generally acts as a close adviser to the president. The Council provides the president with a useful foreign policy-making instrument that is independent of the State Department. This is the foremost model of a nation-specific national security organisation. Each nation has different norms and approaches in national security matters based on perception. The national security organisations and their performances are not identical. Some such organisations change with respect to the governments even internally. There is no consistency since the idea of national security has certain specificity with national requirement. But the designs may have their own limitations. Most of the national security designs are exclusively engaged in military security matters and diplomatic affairs in international relations. The concept as seen today varies considerably.

It is the well-being of the people that is hidden in the idea of national security. But it needs not be the same always if one believes the concept of national security stands for power maximisation and not maximising the human well-being in a people-centric society. It could further change with respect to national psyche and the threat a nation faces. But in its pervading form, national security is the ultimate in human well-being.

National security is an expression conjured in duality—two words amalgamated into one term. Once separated, the meanings of the words individually will be different from the combined term. This is the primary principle on which this finding is based. Nation and security, if taken apart, singularly stand for different meanings.

National security is a conceptual entity, and it is different from the security of nations as can be seen from the difference in the statements, “I see what I eat” and “what I see I eat”. A practitioner or student of national security should be clear about this conceptual difference. The term national security depicts a single concept that is defined in this book. It is a measurable entity that is a function of time and the identified elemental ingredients operating in different terrains. It has certain constituent elements that together in a complex network can prepare for national security maximisation (NS_{max}) by appropriate governance. The accountability is with the government, whatever type, shape and nature the government may take. The people cooperate as members of the formal group in a nation. The concept is limited to the nation and when it goes beyond, it transmutes into a single principle called global security. Global security is an entirely different and highly futuristic concept with respect to national security. National security concept itself is not developed. The idea is quite nascent in human governance. In case it settles down and is accepted in its totality by the governments and the people, perhaps years from now—that cannot be perceived today—the concept of global security may prop up in the minds of the people. However, its entry will be at a time when the demands are different and most probably external to it. The concept will originate when the demand for survival comes under extreme pressure that may turn the attention of the world towards global security. The concept of global security and its governance is not wishful thinking, but practical appreciations of what the world may perhaps witness after a few generations. Things are not going to be easy anyway in the new world as it has been seen that appreciable changes in a human system and the way of thinking are still not at variance with the past in spite of millions of years of evolution. The changes will come slow and unexpected. Visualisation of the effect of change will be slower than the cause and occurrence of change.

The concept, portrayed in a compound word, deals with the will of the people related to their needs physical, mental and emotional needs. It is beyond mere physical security today, though it started with that; the remnants of it can be seen with strategic fixation of nations with the military and war—two totally outdated terms in human existence that can be seen as a major change and still surprisingly unnoticeable. The world today is abhorrent about war and considers it as a primitive engagement by uncivilised people even if that is a superpower unless it is done for killing the brutal instincts of the emotionally uncivilised.⁹ It is stated before that achieving national security to the fullest extent is impossible for obvious reasons. Good governance can only lead towards it. Therefore, the chosen position of achievement objective is maximising national security depicted by the alphabetical symbol of NS_{max} . The mathematical symbol delta (δ) to show an increment in the system is avoided since the attempt is not to express the concept mathematically. It may be appropriate while researching and modelling the subject by scholars.

⁹The quote in Chap. 9 “war is over” is under this caveat. At any time in the world, there will be people who may invoke war. The future wars short of total Armageddon are being brewed seriously at the time of scripting this. Governance by national security can prevent them.

The well-being in national security deals with apparent well-being, not perceived well-being. It is felt in the psyche of the human being. It is a peculiar quality of the humans to perceive more than what they actually need. It is, perhaps, necessary by default for survival. Discontentment in the face of plenty is part of human personality. Contentment in most cases is a state of rationalisation rather than acceptance. The case of national security, being the case of well-being, therefore, shifts towards the realm of human behavioural psychology throughout their lives. The responsibility for the well-being of a human settlement is with the “chief”—the “king”. In national security, the “government” is the “big chief” in whatever form it may be. The responsibility is that of the government as the agent of the people. The type of government is immaterial in national security. It is the will of the government that matters. People participation is important in governance, especially if they are involved in deciding the government. There is an additional responsibility for the people in such systems for governing national security. There will be clashes between apparent security and perceived security at the interface causing rapids in the human mind. It is the apparent security that the government has to see, whereas perceived security is what the population contemplate and desire to have. Governance, even in the most effective form, performs much short of apparent security, and it is from where the perceived security is actually visualised by people, by “I-want-more-than-what-I-have” syndrome. This causes the rapids by early beginning of perceived security. Governance towards perceived national security will be futile and Don Quixotic. The danger is that such attempts will alter course of national planning into shallow grounds. Unfortunately, the governments, more or less on daily basis, promise the unachievable to the people to woo them. Vote banks in an electoral democracy are built on promises that lead to the perceived state of national security. It is a question of attempting to achieve the unachievable. Under these arguments and perception, trend analysis in national security will involve:

- (a) The evolution of the concept over the period of time, even before it was scholastically mentioned or discussed and the continuing changes
- (b) Governance and governing forces
- (c) Changes within the elements
- (d) Changes in the interplay of elements
- (e) Change of elements
- (f) Area of operation of elements—terrain specificity
- (g) Changes in the environment of national security—internal and external
- (h) The global system—the evolving process of globalisation
- (i) The informal hierarchy of nations
- (j) The power factor of the superpower

25.6 Evolution and Changes

The perception of the concept of national security is of recent origin. It was defined and appreciated in many different ways as it evolved. In this book, an effort has been made to enlarge it towards total apparent well-being of the people of a country. Perceived security, which is beyond apparent security, is not a national security objective. Assured physical security was the only objective in the early days. Humans were weaker in their physical survival capabilities compared to other life forms. It was the intellect that paved way for human existence and survival. Table 3.1 (Chap. 3) gives the basic evolutionary pattern of the concept in different stages of random time. It is an arbitrary take, a rough estimate, sufficient to make a statement that the concept of national security is susceptible to changes in time and hence evolves without changing its core understanding—apparent well-being of the people. In spite of this core consistency, changes are certain in its evolution.

From the days of physical fear, humans today live comfortably in nation states within a system that supports their needs including aspirations. There is an informal hierarchy of nations with a superstate¹⁰ at the top and others lined up dynamically below it in a world that is heading towards a better life every day. It cannot be easily visualised unless examined critically. In this statement, the important reasoning is that *the world today is better than it was yesterday*.¹¹ The world has been ever progressing irrespective of the confusion and pandemonium around. If this progress is a sign of advancement in national security, then it could end up in a system that is global. The ultimate concept is therefore global security. If nothing, the concept of national security will be an early reactant to the beginning of global security. It is already there in a world that is growing more and more responsible. The United Nations, in spite of its harrowing weaknesses to command, add with it the inherent problems of alleged corruption and conflicts within, is the only torchbearer in an uncertain world. Chances are that this institution may transmute into a more relevant establishment in course of time by sheer leadership, governance and demand of survival. The process is natural. It is impossible to say whether it can be accelerated without serious research.

Globalisation has become a necessity and is part of this natural evolutionary process. Adverse effects are more visible in a conflicting world. They are widely discussed and published. But the fact remains that globalisation cannot be erased and the governments are, therefore, going to lose some of their powers unless they know how to counter the forces, if necessary. The superstate, presently an idea in the

¹⁰The superstate is a sapient concept in the national security hierarchy. It is not the most powerful (superpower) state but the most responsible and powerful state globally with maximum well-being. The metrics need to be evolved to appreciate the superstate. Presently a hypothetical statement.

¹¹It is important to mention that the reasoning stops here. It does not provide an assurance that the world will be better tomorrow than it is today. This clarification is very important in understanding the principle advocated in this book.

absence of metrics, is not an exception. The status of the superstate ideally is not permanent in a chancy and changing world.

25.7 Governance and Organs

The core efficiency of national security depends on its governance. The idea of governance originated from the concept of governmental system. It means administering the public system including controlling and regulating it. Governance is a term used currently even in managing formal corporate groups. National governance is not just politicking or bureaucracy as many may believe, but administering policies and affairs under regulations and control in a state by a government with an objective to maximise national security. Because it is the duty of the government irrespective of the form it is in. Administration is not governance. It is adjunct to it. Similarly, there are many misgivings about governance, and the blame is on the government when people express dissatisfaction. Though rightfully directed, often the diagnosis could be seriously misplaced in such complaints.

Governance is a serious business that cannot be found faulted at any stage since it is built on faults and fissures in any governmental system. A failure is often quoted as misgovernance or bad governance, which again is a term that only shows a relative empathy rather than analytical acuity. A government has to create an enabling state. If governance is what the governments do, then the purpose of every state should be common. It is not so. There is an anomaly here, because it is the duty of the government to maximise national security. A state is distinctly different from a government, though often it is misquoted. It is the supreme public power within a severing political entity. The governments will change, but the state does not in the normal appreciation. For example, the often-used term, a failed state, is more appropriate to a failed government. Another government or another form of governance by the same government, if willing, could revamp the situation. The governments may change, and the state will remain the same along with its people. In that case, the government strictly will have a little more priorities beyond the states focal point. That is when the government calculates its own existence, and, hence, governance by a government by part is also for its own existence. This gap matters in national security governance. Enabling and empowered governments will be able to converge on both issues effectively. Here, it is important to understand that a particular government will exist only if a state exists, whereas a state can exist irrespective of the government that is in and even without it. But only a government can provide national security. The privilege to go beyond the state's declared objectives in governance are available to the governments. But the common minimum programme for any government will be that of the state's primary objective—governing towards NS_{\max} . If the government succeeds in focusing its governance towards this objective in a balanced manner, its own survival would normally be guaranteed. The priorities and purposes of governments have changed over the years. Expansion of territory, succession, physical security, autonomy, freedom

and independence, welfare-related political systems, status, power, etc. changed priorities of nations and their governments. People-centric national security governance was never the end objective of national governance so far. People-centred national security governance is the only way to superstate status. Power-centred national security may be an attractive proposition but could be short-lived. History beckons in every page of time.

The forces that drive the world towards better days would have been always visible but for the conflicting forces—collectively termed as the anteforce in this study (Box 25.1). The opposing forces that control growth by preventing it will always remain in a system of governance. There are many individual terms used to explain the anteforce that this book modestly rejects since strategic studies in human environment have to be done with clarity and without bias. The terms used to mention the opposing forces or anteforces to good governance are terrorism, militancy, insurgency, criminal syndicates, rogue activities, corruption, incompetence, political muddle, bureaucratic conflict or any other format that suits the wits of the day where national interests are at bay. The concept of and bickering and complaints against anteforces are universal. It cannot be wished away. The anteforce to governance is well embedded in the global mainstream as part of national security nucleus. The effect of anteforces on national security can only be considered as acceptable roadblock in a system process. Such roadblocks have to be overcome either by eliminating the causes or handling the obstacles that are affected. To understand the process better, collectively, it is preferred to call all the forces that counter effective governance towards NS_{\max} as anteforce in this study.

Box 25.1: Anteforce: The Power Within

Anteforce, a term introduced in this study of national security, is a serious concept that needs elaborate research. What is important at this stage is to understand that the constituents of the anteforce, and thereby the anteforce itself, are not exclusively those at loggerheads with national security governance. The government will have to face them as “ante” not “anti” to governance—as a requirement similar to a stake, a price to be paid, say, in a game of poker. This book does not intend to deal more on it since it is subject to further research. The forces felt counter to governance, therefore, is treated as “anteforce” as a stake that support governance towards NS_{\max} but may lower the overall yield depending on the style of governance. Governments will be able to govern using the anteforce tactically as pivotal forces for better yield. Anteforce is a source of energy. The author feels it can be turned to support governance as “proforce”.

Experience from the past shows that anteforce cannot be eliminated by destruction but could be contained and overcome and even converted into proforce, in support of governance. This is visible when a government hosts anteforce for whom

the host itself is ante(force).¹² They will always remain as the strongest arbitrators of national security maximisation in which order is brought by disorder. It is very clear when one analyses a biomodel in actual life. It also indicates that human life within its environment is a closed system in which disorder maximises with respect to time. One reason could be the increase in demographic density of the non-endangered life form—humans, the only one as of now. This is a hypothesis. The time for disorder maximisation is much longer than an average human life.¹³

The increase in disorder in a closed human system should not technically affect the apparent well-being of an individual in it. That is why governance in national security should ideally be an effortless process; it is like pushing a moving object. Generally, there is no static inertia to overcome for a government—that is the good news in national security governance, unless the nation is without a government. This principle is also applicable for any formal human system governance, though this book does not peer into corporate, social or family governance. In mathematical terms, the dynamic inertia of a system can be effectively manipulated in governing that system just like a navigator uses the wind and tide to handle a ship at sea. It is as simple as riding a bicycle that is not stable in static phase. Every nation, corporate house, society or the smallest of a formal group, the family, is under dynamic inertia associated with it. If not, it had been dead and desolated since the entropy would have maximised at an unprecedented rate. Professional governance can be made comparatively effortless by riding over the dynamic inertia of the relevant system.

Is globalisation within the ante force in national governance? There are people who argue from both sides. It is not expected to be since globalisation is part of global growth. It is about global development in the future. But there is resonance in rhapsody, repulsion in fragrance or rather distaste in taste when it is stated that globalisation kills growth and that too comes from none other than the International Labour Organisation (ILO). It came in a news item in 2004. The ILO does not say there is retardation. It only emphasised that the growth advocated wasn't true.¹⁴ The ILO stated that globalisation slowed down growth in many countries including India and China. More crucially, globalisation was associated with increase in economic instability rather than the much-touted economic progress. The ILO found that there were rising economic crises subsequent to globalisation.¹⁵ The report of the ILO

¹²There were reports that China officially hosted Taliban subsequent to US retreat from Afghanistan in July 2021 when there were allegations of brutal suppression of people whom the latter ideologically represents. China attempted to turn the ante force to pro force by warm shouldering. The outcome, however, needs to be watched. It will take time. Tan, R. "China hosts Taliban leaders as U.S. withdraws troops from Afghanistan". www.washingtonpost.com/world/asia_pacific/taliban-china-afghanistan/2021/07/28/fdfbe024-ef88-11eb-81b2-9b7061a582d8_story.html. Accessed 28 July 2021.

¹³The biomodel of death of a soldier in war shows the span of death of a human is shorter in war than the span of the final result of war in its biomodel. This can be applied to larger human system behaviour.

¹⁴"Globalisation has Slowed Growth". *The Hindu*, Kolkata. 2 October 2004. p. 4.

¹⁵Ibid.

drew out the gap that was increasing between the poor and the rich by globalisation. The middle remained where they were—in the middle. While the progress of the middle class was rather slow, the poor suffered more by globalisation, and the rich were accumulating more wealth. This is from the horse's mouth—with the teeth widely bared. The findings of the ILO are based on national income in many countries after the process of globalisation has taken off. The ILO studies show that the trend towards civil liberties through political democracy significantly increases economic security and those governments spending on social security policies also have positive effects. But, measured on a long-term economic growth, has a weak impact on security. According to the ILO, 75 per cent of all labourers live under economic insecurity.¹⁶

But opinions and political assertions vary from the ILO report. One of the countries in the ILO list, India, where the impact was slow had a different story to tell. According to its ministry of commerce estimate, global trade was flourishing to new heights. It was expected to increase from US\$6,363 billion in 2000 to US\$8,048 billion in 2007¹⁷ by annual compounded growth of 4.6 per cent. Export-led economic growth was considered to be a sign of healthy economic growth for a nation. In that case, the exporting sector of India should grow. That was the result of globalisation. Simply put, the pundits do not agree with the ILO prophecy of globalisation. According to the report, the policies of the WTO had met India's demands.¹⁸ This is an old story used only for reference and further examination by comparing with changing times.

Whatever it may be, the anteforce to national security will divert a lot of efforts that go into NS_{max}. Understanding the anteforce is not easy. Often what the governments understand as the anteforce may be a proforce that will be useful in steering national security or keeping the checks and balances in place. Anteforce comprises forces that damage the principles of the concept of national security, if not handled appropriately otherwise. Under the shadow of anteforce, the ideologies will be based on other objectives and not national security. Differences within the government need not be part of the anteforce. They are differences in governing national security. Such forces qualify for being called collectively as the third force that will be useful to the government in all respects.

Gandhi had once stated that he wanted cultures of all the lands to be blown about his house as freely as possible. But he refused to be blown off his feet anyway.¹⁹ In India, 160 Naxal organisations had united once to fight against foreign investment and India's inclusion in the WTO. They were wary of India being sold out internationally. An anti-imperialist convention was organised by two major naxal outfits—

the All India Peoples Resistance Forum and the Struggling Forum for People Resistance—in Kolkata, India. They decided to boycott elections. Those involved in monitoring such activities considered them attempting to group to build up legal struggles against the government that would run parallel to armed insurgency.²⁰ Any front of resistance, if it follows the constitutional path, is not an anteforce. If theory is to be believed, then globalisation and anteforce may make the governments slip on rough terrain. That means governments will lose power. It brings out a new piece of thought—the future of the state under global changes. According to expert views, the state has not shrunk in most of the countries by globalisation and where it has, the retreat is not perceptible.²¹ If that is so, the state does not buckle under pressure even from anteforce. Opinions may vary.

Globalisation's impact on national security, even if the state has retreated from its proper place, cannot be serious because it provides the necessary economic support to people in a competitive engagement. That means the markets have taken over part of the role of the state in national security. Here again the government loses out seriously in its ability to influence. But under the common minimum governance towards national security, the government has the global support in governance. Currently, it is economics and to some extent military matters. Because, the best way to prevent a war is to engage the opponent economically for whom a war will induce economic loss. It does not have to be under a conflict situation. It can be done avoiding a conflict. It is a win-win situation though may not be easily applicable to traditional or ideological enemies. It is only a matter of time the world turns around paving way for economics to take over from the military in direct engagement.

According to *The Economist*, advancement in technology and ideology has made the state to retreat proving unequal to the challenge.²² Globalisation, called in some parts global capitalism, by advancement of technology had shrunk distances and eliminated sluggishness. Does it mean that the age of the big governments is dead? How is it going to affect the concept of national security? Will the global community take on from where the national governments leave by authority dilution under the winds of change? Will the governments be able to regain the lost authority in the future? Will the winds of economic globalisation change direction? The bifurcations point out the trend towards enlarged global participation in the future world. Global security, in that case, cannot be a chimera. But which way it is going to happen? Is it after a total disorder? There is no history of an orderly system unless it was preceded by a serious disorder. In that case, are the signs of global security leading the world to a total disorder subsequent to which alone a global order under a new concept with limited powers to national governments will take place? It will be interesting to watch the change and the resistance against such a process. But that may stretch

²²Ibid., p. 144.

beyond generations. And what if the planet wants all its life forms where they are born to occupy it without borders, if not physically at least by globalisation?

25.8 Elements: Changes and Interplay

The concept of national security defined in this book is a compound string of 16 identified elements. It is this configuration and the interplay between them that are to be studied to understand the process. Studies in isolation will not be relevant to national security. In fact, to simplify this argument, a war (in the attempt of military security maximisation) may have corresponding negative impacts on the other elements of national security whatever may be the outcome. The entropy of the entire system, to use the language of chaos, needs to be kept constant at all times for stabilised approach to national security. A sudden increase in entropy will be disastrous. Entropy cannot be reversed.

An identified element has certain characteristics that make it an individual contributor to the NS_{\max} concept. At the same time, the elements are interdependent in such a way that a change in one will have an impact on the other, irrespective of their terrain specificities. From the line-up of the 16 identified elements, there is no telltale sign that any of them will leave the table in the near future. Nor there are chances of merger of elements or division of an element into more elements. Chances are that the elements may enlarge in their functions and intensity. While national security maximisation is the ultimate objective, maximisation of a particular element will be by taking into consideration its impact of such maximisation on other interdependent elements and optimising such maximisation towards NS_{\max} . In the case of elements, maximisation is actually optimisation relative to the interactive elements on each issue. For example, defence build-up should be with due consideration to economic security, or environmental security should be taken into consideration, while economic security matters are discussed. There are cases where an increase in one element may give a corresponding increase in another, such as food security and health security. Even in such cases, it is only in a limited way because food security may only supplement health security related to nutrition, but not other aspects. Simply put, if every element tries to maximise by itself, the net result could be a reduction in the national security index. The theory is similar to the attempts of various branch offices of a bank mobilising deposits in a fixed customer base by undercutting each other where by the net profit of the bank as a whole reduces under internal competition to peak independently. It is an old management game. The same applies to the interplay of elements of national security.

25.9 Elements and Terrain Specificity

More than 3000 years ago, the Trojan War, seemingly an epic mythology on a real incident of conflict, had the interplay of the sea and the land, in that order. The latest wars have more terrains added to it—the airspace, the contiguous space cyberspace. That makes the 3,000 years, or around 80 generations of human life actually static without appreciable change in terrain specificity at macro-level. It goes through all other elements of national security also. Terrain specificity, therefore, is an important but not frequently vacillating aspect in the trends that may set in the interactiveness of elements. Terrain shift in activities may be gradual. But all identified terrains will be included. Non-physical terrains may move further towards the forefront. Terrain specificity is vital for national security integration.

25.10 Changes in National Security Environs

Dangerous and unexpected changes in national security come up when bad deals of the past catch up. It is also not practical to benchmark national security against all variables. It will be an attempt in futility. Instead, it is better left to the process of maximisation. And if one insists on benchmarking, there are ways to circumvent the rule. That is the attempt in this book. Here one looks at what bothers the people. Anything, yes, almost anything can bother the people and take away their sense of well-being. It can vary from economic health of the country and unemployment in the family to the war in faraway and ethnic wary Armeninistan or oil-rich Mujahiri.²³ The change in the environment of national security is omnipresent.

25.11 Global System and Globalisation

Domination is not likely yield favourable results in the future world. It may have temporary advantage to overcoming a situational challenge, but efforts to dominate can meet with fatal results in the long-term geostrategy of a nation. That will speed up the slide down in the hierarchical scale. This argument can be tested by biomodels of the past. Domination takes the party that dominates to the opposite side—the anteforce in global governance (it is reiterated that the terms force, proforce and anteforce used in this book are related to governance). The human system that becomes or contributes to the anteforce has to be counted separately in the game plan for national security. When a human system succumbs to the anteforce, it transmutes into the killer variety. It cannot be the protector of whatever the system may stand for. Turning them around is the responsibility of the superpower, which

²³ Fictitious countries. For examples only.

could also be the superstate of the day in the hierarchy of nations, since the United Nations will not be in a position to exert the necessary dynamism collectively. Collective security is the hymn, a *mantra* that the United Nations chant to keep the members in a somber state, but not practical as has been proved in its half a century plus existence. There is no *nirvana* in site. Its practicality depends on the time that is yet to be spent in the future. Votes in the General Assembly only give numbers, not the ability to influence beyond limitations. This shows that there requires a bond between the leading state of the day and the United Nations that also include the former as a member. If at all any attempt is made, it is only to suppress the ante-force by power that too in disagreement between parties involved. The requirement is to alter the ante-force to national security process. Such measures have to be applied with the knowledge that the ante-force is part of the system growth towards a much secure set-up—the global security. Converting the converts from the ante-force is the preferred method. That is where the leading state should take the lead with the United Nations or vice versa. That is also a way for a state to become a superstate. That means the prospective superstate should focus on GBNS. There are many states with this potential. They would also be good for converting ante-force to pro-force in the world of sapiens. It is not easy for individual nations to engage themselves in this process singularly. It requires dismantling of external linkages of the ante-force. It is a joint effort.

The world is substantially advanced. In spite of that, people feel greatly insecure. The problem is that with advancement, the perceived security level also increases, whereas apparent security based on human needs does not undergo much variation. It is negligible and, therefore, can be treated as constant. It gets fulfilled ideally with lesser effort. That opens the doors for perceived security wider. That can make people restless. Another disadvantage is that global development is not uniform. Many in the world, and even in advanced nations, are not getting the benefits of advancement. Advancement benefits should even out to people nationally and globally without which even the span of perceived security margin would be distant. For example, while apparent security level requirement of a person in Burundi is more or less the same as that of a person in America, there will be a huge gap between the levels of their perceived security in an ideal situation. The threat perceived will also be high when perceived security increases. For example, Burundi does not expect a terrorist attack of a magnitude, experienced by the United States on 11 September 2001. Yes, there are other threats to Burundi, and some of them could be catastrophic. But the threats as well as their approach paths are different. The threat perception of people causes a major change in the national security outlook. It is coupled with the forward motion of a nation. If this is an unacceptable and debatable argument, it could be placed in such a way to state that irrespective of development, nations may face threats that could be equally traumatic from the viewpoint of the affected nation.

Even though the world is advancing, the changes are not appreciable on a daily basis. It will be clear only when one looks back seriously beyond time. The changes in technology cause advancement. These changes are not strictly trendlines of human well-being from the national security point of view but that of development.

It is also difficult to accept as human development indicators of a nation unless, as mentioned before, the development is evened out among the people. Often it is not. Development adds to comfort, which may have a bearing on apparent well-being, thereby paving way to NS_{\max} .

25.12 Hierarchy of Nations

A hierarchy for the nations or the world geopolitical entities can be charted in different ways. But it doesn't give any special privileges under international law to any nation unless there are established and agreed practices under law, treaties and accords. Nations similar to people are independent entities in their own geopolitical ways. Every nation is an equally dignified entity in the modern outlook under international law. The equity principle is applicable to nations in today's global perspective.

Almost all states have institutional structures, and the people of the world are defined or considered as citizens according to the present-world order that is only likely to refine further in course of time. This formal equality marks a new trend of looking at nations in various hierarchical orders of "who-stands-where-in-what" manners depending on the parameters on which they differ from each. For example, a superpower is a state that is considerable and recognisable by acquired might in military, economic and other aspects of domineering sustainability. They may be called superpowers. There could be a hierarchy based on such parameters in which nations can be brought in sequence in the hierarchy of nations. Another hierarchical order is the position in the binary polarity. The nations with maximum strength in national domineering power will have certain bargaining and negotiating authority that others may agree for mutual benefit and understanding and also in international cooperation. Such nations could form the poles of political axis on which the human system turns around with other superpowers or potential superpowers waiting in line to take over. The other axis based on belief system will be the one that depends on the power of the belief system. The most powerful belief system is religion as of now. Religion is either cultural religion (religion originated from culture) of the original take since the beginning of human system and those who deviated into cultural religions (culture originated from religion) on regimented and specifically structured in chosen faith subsequently. This also includes no-god religious cultures where no-god is the anchoring faith. The shadow of religion also falls on the power axis in the binary. Today, according to the author, the polar powers of the binary axes stand different on the axes of the two poles. The nations which thus stand are hierarchically superior in their respective power projections. The poles balance each other, and the flux between them balances the world in the respective energy fields—political power and belief system (religious) power. No single nation is occupying any of the poles in both axes on date. It could happen if a nation gains both political and religious power that takes it to the competent hierarchical position. Such nation can occupy two poles of two different axes—political power and religious power.

The chances are however remote for various reasons, one being the power of the political power is on ascendancy, whereas the power of the religious power can wane and descend in the future though slowly. This is not further amplified as the study on it is premature and is not seriously relevant here. The poles of the axis based on faith will be dominated by the largest and most powerful faith system. These are only examples on the hierarchical order of nations in a world which is not unified and nations stand to position themselves under various categories in various sequences based on their standing. This is one of the ways to look at the hierarchy.

For this study, the national hierarchic order in the global system of identified entities can be based on NSI as and when the metrics and measuring techniques are identified and concluded under *consensus ad idem* by all nations and its peoples. In such case, the nations at the top of hierarchy whose NSI is high and crosses the calibrated stasis can be called as superstate. Superstate indicates highest and increasing measure of responsibility and accountability in the global context. A superstate will not sway too much on blunt power of weapons or belief system ethnicity.

Hierarchically the superstate is at the apex and others, according to the state of their nations, lining up in succession. This will be the line-up of NSI. In such evaluation, the polarity moves out though the axes of power and faith will still be relevant. In this informal structure, the nation states align in specific configuration dynamically and not in an authoritarian manner where the one on top directly controls the one below it. It is only a social perception convenient to understanding the human system taking nations as the basis with respect to their bargaining power in the world. In such a system, there is motion at all times not only by development but also by demographic movements. This gives opportunity to the citizens of a nation simply to climb up the steps by migration before their own nation reaches there. Often the climb is by skipping the immediate nations above. This system will remain for a considerable period in the future until such time, ideally, every nation is on an equal pedestal. Since such a state is not perceivable, it could be concluded that the informal hierarchy will continue in the world. The hierarchy is not expected to be a hindrance to national security management nor make a nation inferior to another by hierarchy if governed well. The aim, however, is to attain global appreciation so that the baseline of the hierarchy is continuously evaluated and upgraded to higher levels of living standards for the people of such nations. The informal hierarchy, it needs to be reiterated, is not based on the NSI but on development and bargaining power.

25.13 Power of Superpower

The world has to accept the fact that in a hierarchy of nations, even if it is informal, there will be a small room at the top, which will have a very powerful occupant, or two or more outside it competing for occupancy. It is not a pole or part of any axis. There is no unipolar axis. But, the top position in a linear hierarchy. The world is already a witness to this occupation on the Christmas day of 1991 when the United States of America remained critically at the top and the power axis was broken

leading the world to a crisis of sorts without a balancing political power. Many things happened subsequently. The competition was by direct geostrategic combat that involved the military in many situations. The world remained relatively stagnant with respect to the principles of national security. It took more than half a century after the Second World War to change reluctantly. But a peep beyond this span of time shows that the combat between the Soviet Union and the United States to get into this niche was first carved by the latter early in 1917. That was when the United States broke away from its isolationist cocoon in the Great War often referred to as the First World War.²⁴ What brought the United States into this position? The answers are not relevant to the topic of this book seriously. The United States, since then, has been riding the world projecting itself as the only saviour on many occasions—a positive dictum that a superpower and prospective superpowers of the world should follow in the hierarchy of nations. The activities were too many for the United States since then. Facing the fascists and neutralising the Nazis in the 1940s and, thereafter, as it is often stated, containing communism, but not successfully though. It turned out to be containing the Soviet Union. In the chancy war of grit and wit, the United States won over the Soviet Union. Communism slipped out from the mesh of containment without the knowledge of the vanquisher though it will not admit it. The strength of communism has not dwindled in the world. In fact it is gaining more legitimacy in different garbs that are strictly external to the subject of this book. The core is intact. Communism today is very much a recognisable ideology and a powerful political dogma in many parts of the world and in the mindsets of people in the unitary civilisation. Communists are also elected to govern under constitutional systems. It has the power and could pose great challenge to other ideologies of the world. Here is where objective deviation undermines the power of the superpower. It contained the Soviet Union but slipped up in its main objective—containing communism, considered to be the anteforce of capitalism. Think deep, isn't capitalism the other side of communism? Can't capitalism exist in the same frame of communism as in communist countries today? It can. So what's next in economic security? This statement is for the time being.

There are other instances too in the (short) history of the United States where its authority and power as the top gun got diluted by objective deviation. The superpower (as well as the prospective ones) has to understand this and identify such power leaks. Objective deviation could be costly in the long run for any nation, more so for the superpower.

Turnaround came in 1991 when the United States became the sole superpower of the world, but the realisation and plans to put it in practice for a “new world order”

²⁴In fact it was even earlier that the United States has been on to global policing. It first took on the pirates in the Caribbean in 1817. But for all practical purposes, its entry into the First World War, as an individual force to regulate it, is considered as the gaining of the ideology of the superpower status for a nation in the world. It is also important to consider it this way since it was the United States that got itself worked towards this objective.

were slow. There was certain method-inertia²⁵ based on disbelief among others. Objective deviation was visible by the absence of firm objectives in the modern “new world”. Attitudinal change came to the fore a decade later when the fundamentalists with their Al Qaeda principle committed a blunder underestimating the power of the superpower. Only fundamentalists will be strategically imprudent to take on a superpower, that too at a time when everything was going well for them—in Pakistan, Afghanistan, Iraq, etc. That brought the nemesis of the terrorist regime in Afghanistan (temporarily?). For the fundamentalists, the reign in Afghanistan was the pinnacle they could reach so far. It was a reign the world watched helplessly and in the twentieth-century disbelief—the destruction of the tallest and ancient Bamian Buddha in the caves, hijacking of an Indian Airlines aircraft from Kathmandu at the ease of buying a popcorn at a Cineplex cafeteria and making the external affairs minister of the country slated to be a runner for superpower to take passage with a released prisoner, enforcing *Talibanism* at every micro-inch of the land, etc. They were unique achievements in the world of terror. There were no such accomplishments by any terror anteforce in the past, that too at that speed. And at the end of it all, they let everything go in holly smoke by sheer miscalculation of over-enthusiasm and foolhardiness. The militant became a comic in an orgasmic climax of cultural vendetta. Terrorists too commit costly blunders. Does the world know? There is humour in militant uniform too. An erstwhile dictator too will break wind when kneeling down to wash the dirty laundry in captivity and look up unwittingly in denial.

The result of the attack made the United States, perhaps for the first time, to see itself in the mirror of reality. Exceptionally, they acknowledged terror and defined terrorism properly—“one person’s terrorist could also be another person’s...” But more than these findings, what they observed in the mirror was their own position as the only superpower of the world. It was awe-inspiring. The resultant rampage by sheer confidence not only finished the *Taliban* regime in Afghanistan (temporarily as of now) but also annihilated Saddam’s Iraq that was not even involved in sharing a stinking saliva laced hubble-bubble hookah with the terror group. It was a clever manoeuvre of opportunity diversion. There was no objective deviation here. It happened in that way, perhaps, for the first time in the history of the United States. For external observers, it may be a superpower going berserk throwing caution and concerns of the rest of the world to wind because the national security in its perception is based on monochronic power maximisation—without concern for others. Besides, it was the first time the United States came under attack on the home turf after the shocking Pearl Harbour attack (was it?²⁶) on the fateful day of 7 December 1941. It became a question of self-esteem and saving face for the United States, the superpower. Under such circumstances, it is self-interest of survival at any cost that guides decision-making. That is how superpowers have to behave. It was

²⁵The word method-inertia is used to explain the process of remaining stuck in the past instead of visible changes.

²⁶It was not if the government knew about the attack.

clear to President Bush Jr. and the people of the United States who had just one objective—take on the anteforce to the United States and its principles militarily, now. This time they did not slip from the objective. Power also meant wealth generation and accumulation. The power of the superpower cannot be underestimated. The problem is how to channelise the power towards global well-being especially of those at the lower levels of the informal hierarchy? The United States, the most powerful and not so benevolent²⁷, will face threats. It may not face a barrage of missiles with precision weapons that can hit a buttonhole. The fundamentalist may challenge everything dancing on the pinheads that the powerful knows how to make slippery. Well, an odd attack even with a dirty bomb has some limitations and the fury that it will fan will be fathomless. A prudent terrorist (“If prudent, why a terrorist?” is a hypothetical overstatement) may certainly know that it will not be wise to take on the superpower at any cost, at least not directly. Toppling the superpower to pave easy way for the next one in line will be the best bet. That needs good time; but patience is what the terrorists or similar human incendiaries²⁸ lack. No time; that is their weakness. They are short-lived people. They lack time and patience to think cautiously. “Act first and think later if survived” is the motto of the common human brain carried forward from primitivism; for the terrorist, it seems to be “act first and think never”. That is worse. The block is too strong. Within this imbroglio, the superpower and the prospective ones will have many reincarnations without dying.

Contrary to popular belief, a superpower is not a superpowerful entity. It has super limitations too. Certainly the superpower will have the power to influence and bargain on the world stage, but taking the vulnerability factor in the power equation of states, the superpower is virtually helpless. Geostrategically, it will be the most vulnerable nation in the world because it has the most to lose. This can be seen from the criticisms the superpower goes through at all times. The critics are internal as well as external. Criticising the superpower is a business by itself. Every nation and majority of people will view a superpower with suspicion. The United Nations is strictly not comfortable with the Orwellian way the United States use to meddle with its affairs. The projections speak loud. Will it be an isolated case with the United States or will it equally applies to other superpowers is yet to be studied. A biomodel may throw some light on it. At least this could be a lesson for the aspiring superpowers that are likely to contest for the top post. It is yet to be seen whether a nation has to struggle to hold on to the top more than the struggle to reach there. The axis principle always takes the load of this imbalance with the other polar power counterbalancing the excess. That’s the reason why the polar system balancing is an actual in human systems anywhere.

The twenty-first century is in no way better than the previous ones as far as conflicts and disturbances are concerned, though the world is a more comfortable

²⁷ Author’s view in a lighter vein.

²⁸ The term incendiary is chosen here to explain all those who act under quick violence without concern for human lives similar to terrorists and their strikes.

place, and probably less cruel and demonic. The danger of a major global war is not receded, according to British historian Eric Hobsbawm.²⁹ He feels the United States is megalomaniac without a rational foreign policy. The government in Washington, therefore, becomes dangerous to world peace, he feels. The United States has insecurities about its economic dominance since the centre of gravity is shifting away from it to Asia-wards.³⁰ Unlike in the past, today, states, including the superpower, do not have complete control over economic parameters. Growing reach of transnational corporations is curtailing state power even in matters of physical security. States are abandoning almost all the aspects of physical security including running prisons. According to Hobsbawm, the United States has seized the 11 September 2001 opportunity to expand its hegemonic interests in the world by disguising it in an emollient cream of tact.³¹ Seizing opportunity is not only an act but also statesmanship for any government. The superpower has to have its object very clear: to remain on top irrespective of the threats. Seizing opportunities to face threats is one of the ways of strategy. It cannot be attributed as blame. The superpowers, whoever it may be, will be able to win any war once they reach that stage, but the tragedy is that it can never win peace—the feel of it—even after a war. Hence peace for them will be war, and it will remain that way till they withdraw. The war should continue. It is in this effort the superpower will drain its power, money and public goodwill. Therefore, its ability in remaining in its position to some part also remains with its ability to win a war without fighting, if it is not capable of brokering peace. The superpower could finally be ditched by all nations. The problem with superpower, whose power lies in its preoccupation with force, will be identifying an enemy. Fighting a non-state actor (Box 25.2) within a state had started with the invasion of Iraq in 2003. This may not continue because the nations have learnt a lesson and the UN have not depleted its strength. The prospective superpowers waiting on line may better understand the follies of the crown of super status.

Box 25.2: There Are No Non-state Actors

This is the view of the author, expressed in various forums³² and also from career experience and strategic research. Every person termed a non-state actor

(continued)

²⁹ Kapoor, M. “With Irrational US, Global War Can’t be Ruled Out”. *The Indian Express*, New Delhi. 18 December 2004. p. 4.

³² Paleri, P. “Non-state actors and challenges to maritime security”. Author’s paper presentation at the conference titled “Security dialogue: rethinking security in the 21st century” organised by Rajasthan Police Academy at Jaipur, India on 11–12 April 2014. As stated by the author, “The oft used term, ‘non-state actors’ is a misnomer. They never act independently or in isolation. They are normally backed by recognised states and agencies. Hence, to address the challenges posed by such

Box 25.2 (continued)

has one or more supporting state actors behind, including own state authorities mostly for reasons of vested interest under sleaze and power. Non-state actor, hence, is a term of convenience.

The anteforce to the power of the superpower in its natural position is expected to be the combination of those forces that will destabilise its position. Most of these forces will not be directly aimed at it. They will be in the process of evolution as a national or regional power. The power is primarily derived from economics and technology. There are other factors too. Technologically, the superpower is expected to be the leader in most of the cases. But technology could shift elsewhere. Similarly, the economic centre of gravity of the world in globalised environment could shift out of the superpower state. These shifts can bring serious decision conflicts within the superpower. If the superpower does not appreciate these changes in the right perspective, it is likely to make grave mistakes. One of them could be over-dependence on military power. Another interesting phenomenon in such cases will be the criticism it will encounter in the home base, which is internal to the nation. The business of criticising a superpower and its governmental actions will be more vociferous within the nation itself. In other words, the anteforce in the power of superpower will mainly be within the state rather than outside it. What are seen outside will be rather threats or resistances to its ambitions towards national security, whereas that seen inside will be the destabilising forces to its status as superpower or prospective superpower.

The superpower will do well if it learns that it has a responsibility beyond its shores towards the well-being of the world in its passage to global security. There is a misperception in its thinking that its national security is within the limitations of the world and not contained within its state boundaries extended to its citizens including those beyond. It should know that it has to support the United Nations in making the world a better place to live for all. The United Nations could very well be its agent of change for bringing the well-being to the world and not by itself. It should not consider the planet belongs to it and behave like a super cop and terminator in one as the final arbiter of the judgment day. The resources of the world are not in its exclusive disposal. It is not a bully in the crowd of refugees at a food camp. The world belongs to everybody. Instead, if it remains on top with only the aerial view of an eagle and not an elevated view standing on the ground, it may find itself on the ground. An eagle is an elegant bird of power and grace. It should never aspire to become a vulture. It is the law of nature and what history has proven. It can also be proven more appropriately in a biomodel. But unfortunately, that is not going to happen. The world has to witness many nations dynamically moving in both the directions in the hierarchy of nations and, therefore, the superpower can be replaced

actors, it is important for governments to take on such states and agencies under strategic terms, nationally and internationally”.

by another. Otherwise the hierarchy will be static. It is a very unstable situation. The superpower is bound to make mistakes that can crumble it. The next superpowers will have a major task on their way up the climb. It did not happen when the first superpower rose to the pedestal. The changes followed in the world, disintegrations, en bloc conversion of states into different alliances, etc., were disastrous to human-kind, if not to the world in totality. The good news is that once a nation becomes a superpower, it will also know what it has to do to sustain it. And that is a clause where survival is written. What it has to learn is how to unwind the anteforce. Anteforce cannot be eliminated. No assassins have ever stopped the world from not repeating the causes of assassinations.

25.14 Nation-Centric Application of National Security

The consequences of national security policy will depend upon the original perception of the concept on which the policy is based and the direction in which the nation is heading. National security application will be based on the national needs and the way the government has perceived it. The perception could be centred on many issues: political power maximisation; religious (faith system); staying power; succession issues; dynastic rules; political existence; individual survival; dominance; annexing or controlling territories; enhancing military power; national power maximisation and any other objective that the one that has the power decides other than focused well-being of all. Even if well-being is primary, according to this study, it will be limited to apparent security. National security is considered the concept that will provide for the apparent well-being of the people of the country. To that extent, the national security explained here is people-centric with apparent security at the centre laced with perceived security. The concern of governance-based national security is towards the well-being of the people individually and socially. The individual human becomes important, and it is, therefore, seen external to the governing system. The people—the agent beneficiary—stand outside the system, the agent, that governs. The agent beneficiary is more or less internal to the system of governance.

In this study, the agent beneficiary is the people. However, this book advocates and calls upon people in an elected democracy, or even in other types of democracy (governance) to partake with the government in maximising national security. People should understand that they are also part of governance and, therefore, internal to the system irrespective of the type of governance followed. Considering the world is a global interactive and noisy market place, it will further impact with the international concept of national security and direction of the global system. There are too many variables here. Therefore the concept requires to be understood clearly. It needs to be defined unambiguously. There is no room for either optimism or pessimism while analysing the future. It has to be governed by the reality factor, as if in medical diagnostics. The future has to be seen, perceived and examined pragmatically. There can be many opinions and predictions without the backing of

analytical seriousness. A thumb rule is what has explained in the earlier chapters—the changes for the short term will not be easy to notice but the direction will be forward. There will always be headway. This is based on the immediate past and historical evidence. Such findings are to be done scientifically and incorporated in the efforts towards NS_{max} . The bottom line in national security governance is to do it with clarity of vision for the future. This will call for:

- (a) Strategic assessment of the future of a nation
- (b) Strategic assessment of the future of the world
- (c) Incorporation of the assessments with respect to each element of national security
- (d) Implementation process of national security policy
- (e) Continuous review of the policy
- (f) Steering the process through the future

Most of the problems the world faces today would not have been there if such policies have been adopted in the beginning when a nation state steps out on its own. But it is not possible in a unitary civilisation in a moving worm tunnel. It is from this dilemma the lemma of the unitary civilisation in a worm train originates. Close observation will reveal that almost every nation had at one or more times changed its tack without any consideration for the winds of change totally, since its beginning. Those who had to change lesser times are more powerful and developed today. A change through a serious review to adapt to the new is acceptable, but a total deviation from the original policy shows that the entire process in the past has been discarded being totally destructive to national policy and objectives. It is testimony for the absence of vision in governance ab initio. Though an admission, it is a lesson for all. Any strategic plan, whether military or non-military, has to be consistent in a nation's progress. Serious changes at a later stage will be disastrous in its race against time. Such changes mean that the nation has lost crucial time in its progress. A country celebrating a century of its existence may be just 10 year old in its progress with constantly changing policies. Mere existence is not an indicator of progress towards well-being. A nation needs considerable intellectual guidance from professionally trained and experienced strategists for this purpose. Still it can be attacked from within and destroyed by the “barbarians (Box 25.3)”.

Box 25.3: Where Do Barbarians Come From?

From within and not from another planet is the author's answer. “Barbarians” was a term coined by subsequent historians when history had already turned legend if not myth. Here “barbarians” as a term gives a feeling of unshaven heavy people carrying equally gaudy weapons and butchering through helmet, shield and armour in black and red. Black was their historically projected colour as if camouflaged to face battle. The whole visualisation of the carnage will be dark and gritty. Barbarians come and bleed the more sophisticated and

(continued)

Box 25.3 (continued)

perhaps white- or brown-looking men and well-endowed women dressed loose to amplify their endowments for commercial value of the viewers in a presentation, all in bad taste and state. Barbarians thus become bad if not ugly and are present everywhere. They also don't brush their teeth but still have strong ones. This image is from the author's viewpoint of how the pharaohs of Egypt, much advanced according to the period in affluence as well as flatulence by overeating exotic foods, some of them toxic as on present-day considerations such as red meat, etc.

The ultimate finding here is that the barbarians where from the same group in the moving worm tunnel end of the unitary civilisation that was surging backwards or astern, shaking up the system. This also proves the unitary civilisation concept as well as the movement of human system in fore and aft surges. Those who prime moved the backward surge where at the tail end of the unitary civilisation and hence lesser advanced people than them according to the title barbarians. They were considered quite backward by later year historians.

The warning here is that the human system moving forward in a unitary civilisation inside and along with the worm tunnel will have regular clashes within them which perhaps the more advanced may not appreciate at the particular time. Some of the clashes can become their nemesis later to be known from future historians as succumbed to barbarians or their equivalent. Governance can avoid such calamities by taking them as anteforce and translating into proforce by governance. Though not as easy as elimination, it is a preferred choice of modern governance for better results.

Each nation, depending upon its position in the hierarchy of nations, has to appreciate its national security requirement to draw a policy. For this, it has to understand clearly where it stands at a particular moment in time to estimate the distance it has to traverse or change course. The key trends in the world in general have to be watched like a hawk. Such trends may have many things common in history. For example, terrorism, the much talked about subject today, is not something new. Nor were ethics in war. There were war-free days between nations in a week in the olden days so that the people could go and stock up their food for another week that would restart spilling blood over the streets. Today, the free days are replaced by withdrawals in bad climate, peace talks and ceasefire to gain time for reinforcements and further thinking. Here the trend is to be seen whether there is any indicator that the terror today is continuing the same way as in the past. If so, it is an indicator that terrorism cannot (easily) be eliminated but can only be contained. As long as the containment is in force, whatever may be the method, terrorism will stay out looking for an entry. The trend in terror and violence is that they are presumably on their way out, in one argument, with its peak stage already over. This is an untested hypothetical statement. And also with a weird feeling that something more

serious than any attack so far may strike one day. This assessment is based on the psychology of the perpetrator who, if the indicators are to be believed, has understood that the strike made things more complicated and defeated them. It is a situation where there are no winners. It is based on a dictum that terrorists will strike until they win. And terrorists will never win; so they will strike always. It could be termed Don Quixotic. But not clear at this stage. But Don Quixotic behaviour is real. This finding is also based on heuristic inputs that indicate that terrorism in the world and associated activities are not individual creations, but well-planned promotions with ample money and training facilities behind it. The merchandise of terrorism will spread from fear for life and hostage situations to economic centres and brain banks of the victim nations globally. Considering that the anteforce related to terrorism will never die, it is not killing terror that matters, but caging it through dissipation or uprightness. The world could inform its inmates with a billboard, “Heaps of fireworks ahead” on the highways of time.

Strategic thinking always had a tendency to consider the world becoming more dangerous than before. It is only an assumption. Isn't that way the world has been thinking about it in the past? The same ideology is also found in estimating budgets. An organisation estimates to increase budget appropriation from the government. The return from such estimates is what the government should be concerned about. It calls for strategy audit. Unfortunately, the governments do not know how to audit their organisations for returns to spending. It is the same with the organisations themselves with respect to internal audit. They may audit expenditure for procedures including vigilance compliance, but not for operational returns. Without such audit, the government will be devoid of a mechanism that assures return on expenditure. Internal and external strategy audits on returns are important to prepare balance sheets of organisations with respect to their effectiveness.

The superpowers and the United Nations ideally have the power to influence the world. While the superpower will have a stake in the pie, the United Nations will not, since it belongs to the world. It may not have the kind of bargaining power that the superpower will have—at least for some time. But still the influence of the United Nations may prevail in the long run. According to the trend, the power of the United Nations should be progressing at least linearly, if not in a dynamically progressive manner, whereas the power of the superpower ideally will remain constant or decline in course of time. But the gap in the influence between the United Nations and the superpower is significantly large with the latter having a definite advantage over the former at all times. The position of the United Nations is paramount by its well-prepared charter poised for further changes. Currently, there are situations in the world that can only be handled by midway solutions—between chapters in the Charter. There were situations when the United Nations would have felt the need for a few more pages between Chaps. 6 and 7 in its Charter, often referred to as Chap. 6 and half to overcome its handicap in intervention.

The world certainly is not heading towards chaos or disorder (even then there is no serious danger, because disorder brings back order in any chaotic system very fast and the world will be a better place than it would have been immediately after chaos). In some quarters, there is talk about integrative and disintegrative dynamics.

It is also not clear. What is obvious is that situations, whatever they may be, will be exploited.

War, economic crisis, energy crisis, disasters, environmental crisis, transnational crimes and corruption, changing mode of technology, formation of governments, integration and disintegration of nation states, border disputes, upward and downward movement of nations in the informal chain of hierarchy, increasing gap between the rich and the poor, globalisation and control of the world by corporates and individuals, ethnic conflicts and the restless anteforce determined to destroy the left over tranquility in the midst of chaos—that is the world: past, present and future. It sums up in one word—unchangeable. Changes will be on the surface; at the core, the world will remain without much appreciable change with respect to its human inhabitants about their physiological, mental and emotional needs. In fact, without change, it will remain a drag for strategists who have to look into relatively “smaller” issues like ‘terrorism and nuclear proliferation’ without an answer.

The United Nations will be watching, and over its shoulder, the superpowers will survey for their own survival. These entities have a responsible job to do—prevent the world from plunging into turmoil. This, the world expect them to do very well. They are capable.

The intent in national security trend analysis is to ignite the thought process among the mentally agile to diagnose the future trends in national security. A running hypothesis is that the world will be different tomorrow with respect to threat perception. In a biomodel of the day, one can see that the threat perception remains unchanged today with respect to the past except in form and shape. Therefore, in future too, it may continue in a different form with the advancement of technology and lifestyle. The world will be a more miserable place is another hypothesis. If that were so, the world would not have progressed in this manner in the past. The world should certainly be a better place because human beings are getting advanced, and the need for keeping the world that way will be paramount. The world may be caught off guard is another statement. It is possible because the world has been caught off guard in the past too. But the resilience of the humans will certainly surpass any surprise. These capabilities are by default and humans do not have to struggle too much for that. Under these conditions and many others, one can explore to estimate the world of the future. What stands clear in the middle of self-indulgence in human life is the concept of national security. The concept will not get erased in spite of problems in its implementation. What is needed is total acceptance of the concept under the doctrine of well-being. Apparent well-being is the birthright of a human being. Denial is not acceptable. The role of the government is to provide it. This awareness is not likely to dawn upon many governments in the near future. It is imperative for a government to understand its accountability when it is a matter of protecting its citizens and providing them an anxiety-free life by simple steps to the level they apparently need it and not the level they perceive or want it. In the world today, there are children who commit suicide because they find it difficult to bear the stress of competition. In another part of the world, school children, under extreme pressure, shoot down their classmates in the schools. The governments have a role here. Where the governments cannot reach out, there is the global community under

the United Nations. The international community has to rise to this occasion with all their might in whatever capacity they are—the world's rich, powerful, scholarly or just ordinary with not titles to go by. All have equal responsibility to make the governments work towards NS_{max} .

Irrespective of a changeless world at the core level, international systems are more unpredictable today than they were before. This is a major thrust area for policymakers. Many nations in the world are internally imploding by weak governments and social strife. The United Nations and the superstate have serious roles to play in these conditions in getting them back on even keel by controlling the anteforce within those nations. Once this is guaranteed, stability in predicting the international systems will be achieved.

25.15 Premising Nations Under Continuum Principle

The continuum principle advocates the human system or the concept of evolution is continuous and when interrupted after a span of time reprogrammes itself and repeats the continuum in the new format. This continuity format will never end but gets reformatted like alternation of course in a continuum passage. The subsystems within the system may alter and give a feeling that the system is shifting. A human system is continuous once it is formatted, but the subsystems within it need not be. They will keep altering in form, character and profiles sometimes totally disrupting the direction of the forward motion like the movement of a paper boat in a narrow stream. It will hit the banks or other turning points and turn around and follow a new course based on the force acting on it. This happens in a dynamic system whether micro or macro. It happens in human life too. The extinction of dinosaurs altered the course of the macro-world but did not destroy the main system—the planet remained as it is. This can happen to a human system which in relation to the planet is a subsystem.

There are 263 geoentities according to this study (2021) as subsystems of the global human system. It will change in the future. Each had a beginning somewhere, sometime. They should also end sometime, somewhere in some fashion. Most of these systems had undergone alterations of their courses in the paper boat existence and continuum streaming. The time span since the end of the last alteration of course till the next alteration is the continuum phase or leg of that nation. This span of time indicates the continuum difference among the nations. It matters a lot in governing the nation. The span of continuum is very important in a nation's life to understand the inherent structure of that nation vis a vis its supporting human system. The span of continuum is adjusted to the last major disruption when the course was totally or distinctly altered. Partial alteration doesn't disrupt a nation's continuum where a nation is what the generations of human system perceive even if it is a Westphalian state today. This, according to the author, is the continuum principle among many factors that should assist decision-making in national governance towards maximisation of national security. NS_{max} is a common end objective or goal for

all nations. But their approaches towards it will be different. One of the factors that will affect the approach is the continuum principle. The continuum principle could be in any system approach but is most applicable to human subsystems. Another aspect in decision-making in governance comes from the premise one can adopt between the nation and its people.

25.16 Premising Nations vs. People

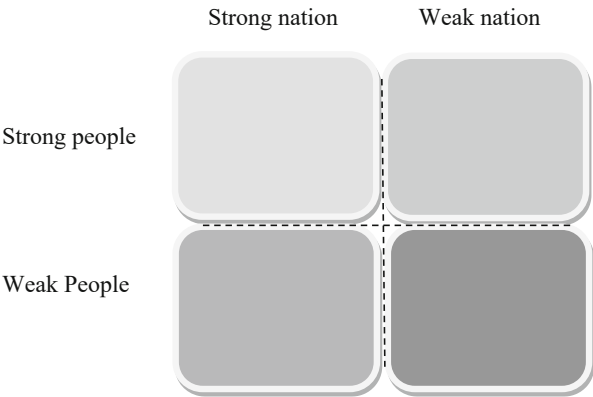

Personality is the conditioned behaviour pattern of the people. Being a behaviour aspect personalities are changeable. Citizens and associated people's personality, functional to time, thereby, is another key factor like the continuum of the human system. The mutual relationship in the life systems, say, a hermit crab and a sea anemone, where two entirely different living entities or life forms exist comfortably for self-existence is an interesting subject of nature. This can be applied between a nation and its people accepting the nation as an organic, thereby, living entity different from its people. Nation for that purpose has to be seen as a living entity separate from the people of that nation. A nation is a geographical space with all its associated tangible and intangible endowments that allow life to survive. But a nation is not a nation unless it has people and is governable. Just like a corporation, a nation is an exclusive entity. People provide identity to their nations that in turn are mutually shared by the people. In this condition, under the context of geostrategy, there can be four different kinds of classifications in terms of mutual existence in the case of a nation and its people:

1. Nation more endowed than its people (nation stronger than the people and hence people depend on it for support).
2. Nation less endowed than its people (people stronger than the nation on whom nation depends more for support).
3. Nation and people are equally weak in endowment (both the nation and the people are weak and struggle to exist).
4. Nation and people are strong and support each other.

This can be shown hypothetically as a window for explanation (Fig. 25.1). For this explanation, the endowment for the nation means various factors that include the continuum span, resources, geolocation, culture and the position in its life span since origination covering the two aspects of growth and decline that may or may not culminate in its macronisation or micronisation.

The situation at the macro-level is based on one of the four windows within which a nation's geostrategic strength will vary. The windows can change in course of time. The government and people should be able to appreciate it all the time. The target for the government is to bring the nation to the ideal situation of strong nation and strong people. This can be done by governance by national security.

Fig. 25.1 Nation vs. people window

25.17 Twenty-First-Century Paradigm of National Security

Viewing human life as a system continuum will show that nothing has changed at the macro-level. The continuum extends to date without disruption and alteration of course since the days of living under or over the trees and moving into caves, when the rain storms came, to the present-day luxuriously smartened villas, towers and workspaces except that the terrain specificity is widening on the inkblot profile. The law of invariance ensures (read passively) humans don’t feel the change when it happens. It helps to maintain the continuum unless it is a total disruption. Humans experience delayed sentence. Nothing happens without a reason; therefore, there should be a reason for the law of invariance and also the law of limitations. Delay seems to be necessary. The widening terrain specificity coupled with continuously increasing demographic density, in spite of multiple murderous defaults embedded in a human system design, is what makes the jobs of governments difficult. Their intelligence is not proportionately firing up with the demands. It is the same with those governed; hence, they are not able to maintain the necessary checks and balances.

The twenty-first-century human cannot be much different from his predecessor who survived in the caves in intellect and neuron configuration but for data acquisition, collation, storage and processing.³³ The rhythm of development cannot be on fast track. It has to have a natural frequency (ω)³⁴. But there is a need for human to drive human system existence rather than remaining a passenger in the process of governance. The new century in which the author believes in his quote “war is over” is the post-C19 world that may eliminate the weak in everything and keep the strong formatted further for living till they die (everyone has to go and be replaced for life to

³³This is not a scientifically backed professional statement but a general appreciation to emphasise for changing the system of governance or future under national security concept.

³⁴The symbol “ ω ” (from vibration dynamics) used here emphasises that the statement is mathematical and, therefore, identifiable for calculation and modelling.

go on), till the next global “sanitisation”, scheduled may be in less than a century or perhaps more from now. Similar worldwide renewals and cleanships were there in the past. The behaviour of people was appropriate to the period they traversed. It may be still earlier as a relapse if the present cleaning and maintenance repairs are not up to the mark. The supporting factor is the increased knowledge density that hones the intellectual survival tool for human systems. The initiatives for turning around the governed in the new century have to come from governments. The principle assumption in this process is that humans are treated as sapiens, the advanced humans, though majority of people may not be as advanced in behaviour in the worm tunnel of unitary civilisation. There is no time for the human system to become equally advanced in behavioural aspects and thereby personality. Sapiens should not go with the flow of natural frequency but lead it as vanguards.

Agenda 2030, commenced in 2015, is the main progenitor of sapien governance for the future. It is primarily aimed at the future generations. It is expected to stand amended for better in the future. It shows the concern of the present generation for the future generations and their well-being seriously for the first time in the history of human systems. Good governance with sapien participation will ensure quality sustainability of humans systems. In this process, there are more for the world to understand for sapien governance:

- It is time to think of governance differently. There are visible signs of human system change in the world from the past approach methods.
- Nuclear weapons are no more weapons but can help the planet in case of a threat from deep space as happened before.
- Nuclear safety is gaining considered importance.
- There may be conflicts between nuclear-armed countries, but the world is sure the use of them will be under self-restraint.
- This also means sanction against nuclear power usage and development can also become a thing of the past in the future.
- Warning of unleashing nuclear threat by nuclear-powered countries as a deterrent will qualify for brinkmanship but will self-deprecate in front of other entities.
- It is time to delete many of the incendiary and irresponsible semantics from normal usage such as pogrom, blood bath, pickup guns, rule through the barrel of the gun, fight to the end, rogue state, bleed the country and so on from responsible dialogues especially in geostrategy.
- The United Nations should declare a sapien vision of the world for responsible governance under collective security as it formatted the Agenda 2030.
- Every time world advances, it is going away from the critical times of the past in and for all purposes. The worst times for human systems are behind and the fog and sky are clearing for the better. Humans may seize the time for early development ahead of the inkblot of development.
- The polarities—political and faith based—may remain ideologically till such time the belief systems erode and humans become independent and more confident.
- Terrorism is waning. There are states exclusively involved in terror promotion. But in reality they do it under Crimes 3+ based on power motives on the two

axes—political and faith. This will continue but will find difficult to hold on to the market. Though justification of terrorism on one hand has become brazen and incendiary, on the other, the world is becoming averse of those involved in it. The awareness that terrorism is the tool of the weak and backward is spreading. The anteforce greatly visible in the terror market can be turned to proforce by effective and responsible governance.

- It is no easier for countries to thrive on conflicts and crimes. But there are places like Pakistan's Darra Adam Khel, North Korea's Room 39 and other similar centres of slush and sleaze that serve as physical pods for nasty governance³⁵ around the world. The global community should be attentive on them.
- Most of the countries are going ahead with mainstreaming development though there are others who venture into upstream negativism which may have to change. It is only a matter of identifying such countries and persuading them to turn round.
- The ideology of hate lingers on all over human systems. It cannot be changed as hate is a survival emotion for humans. Hate cannot be eliminated but can be contained or replaced with well-being by governance. The trend is visible around.

25.18 Summation

The trendlines in national security can be arrived at in different ways. One method is the mathematical model which plots the trend against the NSI and another is in the forecasters model where the predications are based on research and observation of trends in various parameters mentioned in this chapter and more that each nation can examine from their own perspective. There are also the common forecasts based on anxiety that could take the observations far from reality. A summary of the probable trends is given below:

- Nations may falter in their perception and expression of the concept of national security and more in having concerted efforts to improve the well-being of the people according to its maxim.
- National security will continue to be a politically driven concept with military security at its centre, especially in nations where the military is either ruling or has direct control over the governance of nation's affairs.
- Another reason why the military or other armed forces will not be disbanded easily is that the "kings" or the governments feel considerable security with them around in their own existence, and in some countries, they are very well and frequently employed for suppressing the so-called internal disturbances (to the government).

³⁵ Nasty governance is governance in unlawful and inhuman manner (author).

- Where the governance is by force, force will be at the centre of national security decisions.
- Nations will change tack, and policies may change abruptly.
- Many nations are yet to resolve and settle not only their border disputes but also the size and type of governments.
- The superpower is the term for the most (militarily and economically) powerful nation today with the highest bargaining power. The trend will continue for a long time. The superstate may make its entry very slowly.
- Many nations with large number of immigrants and demographic stress may find their continuum stasis getting breached.
- The race for the title of superpower will be persistent and can be seen clearly on the track where the nations stand at least as front runners giving an indication of who will forge ahead and who will slip back. It will be more on the political power axis than the faith-based axis in the binary polarity.
- Terrorism, in all probability, will continue causing death and damage that may make strategists believe they are part of the balancing force in the world. Terrorism will transform their ways of engagement. Terror can only be contained. People may develop a certain degree of terror indifference. There are evidences both historical and futuristic. There are proposals for terror betting.³⁶
- Countries are more likely to micronise than macronise in the future. That means increase in geoentity counts in the future.
- Superpowers may be concerned about holding at the top at any cost. In this process, they may shorten their life span as superpower if not careful. The right method is to shift gear along superstate gradient. It means the need for GBNS.
- The concern of the world towards national security will be on a day-to-day and contemporary problems rather than long-range vision, because the countries will not be able to get away from the daily strife of governance. The panic and confusion during the Covid-19 pandemic was an example. The world may be preoccupied with conditional situations of terrorism, refugee influx, nuclear apprehensions and so on. They may not have time for serious GBNS leading to NS_{max} . For security as an instrument of total well-being of the people of a nation will take backseat in its original form.
- Many nations will not even have a national security strategy in place and will remain with the support they receive from elsewhere in governing their nations.
- Developed nations will go through identity crises in the race with the superpower.
- Ethnic security debates will not only continue but may also go for correcting past mistakes that may find objections in the future.
- Global security as a concept is already validated, but its absolute acceptance and implementation will remain a distant aspiration.

³⁶R. Sukumaran. *Cryptology, digital assassination and the terrorism futures markets*. Strategic Analysis. Institute of Defence Studies and Analysis, New Delhi, Apr-Jun 2004, Vol. 28, No. 2, p. 219.

- The world will evolve into a better place, but total national security for the people could remain a distant but not an impossible dream.

All these forecasts in the book are to be seen with caution and used only after experimenting with the signs available globally or with respect to the specific nation. The major trend in national security is the inability or rather reluctance to accept the concept directly as a people-centric subject. It is not likely in the near future because the world has not understood a common policy for achieving the total well-being of the people. Reasons are many. Yet identifying the process and preparing a recipe for total apparent well-being are what is examined in this book. The trends are that the nations will practice national security the way they have perceived it. Most of such perceptions will be military-based diplomacy. Maximising military security by power build-up will be the sole motive of such nations until they are no more capable of going further. Saddam Hussein, the erstwhile president of Iraq, is an example. Under such situations, the nations will be tempted to stockpile weapons of mass destruction including dirty bombs by crude designs. (This statement doesn't mean Saddam did it.) Any other form of national security will be power maximisation with national governments trying to accumulate power with themselves under misguided national judgments. There are chances that a handful of countries may practice national security at higher levels attending to its various elements scientifically. The world will develop accordingly. The nation states will continue under an informal hierarchical system based on their geostrategic bargaining power. Most of them will remain static in their hierarchical positions and move with the trend. A few will roll back from their positions. While all will move forward, a few may climb over others and slip past them ahead. The gap in hierarchy between nations may also widen in course of time. Transnationalism in negative profile will become widespread. The world will certainly rise to the occasion by designing more comprehensive policies to face the challenges under empowered governments.

Chapter 26

Strategic National Security and National Security Strategy

Strategy and tactics are the long and short of competitive game plans where strategy rides over tactics in all applications. But is there a need to strategise tactics?

26.1 Introduction

There are two seemingly identical terms in this part of study—“strategic” and “strategy.” The terms are vastly different in application and design. They are not similar when applied to national governance or any other competitive activity. In fact, the government or the concerned human system will require exclusive expertise to craft and implement them. Therefore, appreciating the difference between the two is vital to engage an activity competitively in a human system.

The highest and most compounded activity in a human system is national governance. It is at the macro apex of the activity pyramid. Governance is what a government is expected to perform. Nations are the largest and most complex human systems to govern. Governance of their respective nation is the exclusive activity mode of global community. Global system activity is a collective objective of nations aimed at independent well-being as of now and in the long future ahead. The global human system doesn't follow the unitary principle—"one community." Terms such as "one world," "world peace," "collective security (from whom or what?)," etc. are abstractions. They are illusory statements, if not conversational pieces. Such terms do not find place in strategic governance as they cannot be defined precisely. But they are not unreal. Insecurity within the human system is real and present. It is common, and the humans are chillingly aware of it to the telomere.

The global community, without being a unitary community, functions independently as geopolitical entities, each in a separate niche for collective well-being. They need to compete for survival, and more for well-being. Every other activity within the national system falls under the umbrella of national governance directly or indirectly. This study revisits national security concept including that the author had proclaimed years back (2002).¹ The attempt is to modify the concept with respect to the ongoing scenario as it is time for universal intervention at least by those who are convinced on a unified format for a globalised world where strategic national security (SNS) with a long drawn-out national security strategy (NSS) is appreciated for competitive governance aimed at human well-being. Governance needs a common format for convenience and standardisation even if not followed by governments, in which case it becomes a reference to assess deviation. Governance is not an easy task; the governments should know. Undiluted competence sans prejudice matters a lot in governance.

Competition is inherent in human activities. Invoking competition in an activity doesn't require an adversary within or external to the system boundary. Competition is primate instinct. It is built in, not embedded as add-on. What is necessary to compete in the human system is strategic approach. The adversary is not an entity, but the inherent "imperfection" in the performing activity. Competing against imperfection is necessary for survival. An adversary reflects on the inherent imperfection of the system. The adversary is identifiable external to the competing system. Otherwise, the system has to compete with itself. This principle is critical for crafting a strategy. In national governance, the competition for the government may not be with another nation, but with one's own nation. An example is that of the world's most powerful nation, whichever it is. Ideally it should not have an external

¹Paleri, P (2002). "The concept of national security and a maritime model for India." *Doctoral dissertation*. Department of defence and strategic studies, University of Madras, India. Also see Paleri, P. (2008). *National security: imperatives and challenges*. Tata McGraw-Hill Publishing Company Ltd.

adversary identifiable to compete with, because it is said to be the most powerful.² But if it doesn't compete, it will lose bearing and fall back only to be overtaken by another. That's why it has to find an adversary in itself and compete with it (Box 26.1).

Box 26.1: The Hare and the Tortoise; The Hare and the Lion

The story of the hare and the tortoise was popular during the time the author was a child. But, cannot remember when he heard it first, and from whom. The story is given in the *Panchatantra*.³ He didn't understand it then. But, still vaguely, it looks the adversary of the hare was not the tortoise, but the hare itself. The tortoise benefitted from the mistake of the hare. There is a lot to learn from this story in strategy and tactical planning.

There is another one. About the old lion that was once the king of the jungle but could not run and hunt lately. The lion ordered that the members of his kingdom should depute one among them as his daily food. That was when the hare took over leadership and decided to zap the lion forever. He was deputed as the lion's repast. It went to the lion deliberately late. The lion was angry but the hare submitted it was stopped on way by another ferocious lion and had to escape to be the loyal meal of the old beast. Then it took the angry lion to a well nearby and showed its reflection in it. The lion thought its reflection was another lion challenging it and jumped into the well. That was the tactics the rabbit played in the game to eliminate the lion. Here the adversary to the rabbit and other animals was the lion but for the lion it was itself.

In these stories there are interesting findings—the hare (rabbit) is common in both. The competitors for it were different. Both the cases show clarity about the adversary (threat) which is vital in strategic planning for developing associated tactics.

The stories similar to the hare, tortoise and lion indicate the early human perception of the weak and the built-up belief system that the “weak” can overtake the

²This is an idle situation. It doesn't happen because the most powerful will also have a polar opposite in a bipolar system that is equally powerful, well, almost.

³The *Panchatantra*, dated roughly to 1200BCE-300CE, is an ancient Indian collection of interrelated animal fables in Sanskrit verse and prose. The stories of the relatively weak winning over the strong by adopting strategy and following appropriate tactics have been orally transmitted in Sanskrit. This has been based on five *tantra* (strategy and tactics combined). They are *Mitra Bhedha* (loss of friends), *Mitra Laabha* (gaining friends), *Suhrudbheda* (causing discord between friends), *Vigraha* (separation) and *Sandhi* (union). These are said to have been collected by a scholar called Vishnusharma in some recensions. Some others quote the author as Visubhaga who was expected to have been living during the period. The exact dates are not known. These stories are there in different folklores and languages in various parts of the global human systems as evidence to the global human thinking and community concepts which further indicates human intellectual evolution. One such reflection is visible in the Aesop's fables. Aesop (620–564BCE) was a Greek Fabulist and storyteller. India and Greece had been seriously interactive in ancient times.

strong “strong” by sheer strategy. The adversary for the weak is the strong, whereas for the strong, it could be the strong itself. This is important to understand in any game plan, especially in governance. That is why the strong has to compete with itself to keep the “weak,” weak. Competition demands crafted strategy.

Therefore, the problem with governance could be adversarial misconception—simply not knowing with whom to compete. If the competitor is not known, how to compete also goes haywire. This stasis in management or governance of any sort, “not knowing” the opponent or believing there is none, is the gravest mistake in forward planning. In a statement “racing against time,” the protagonist identifies the opponent—time. It is a good move. It is not philosophical but absolute reality to say in life one’s prime opponent is oneself. Identifying the opponent and targeting it are necessary to avoid fighting against a hollow enemy. Competition is necessary for moving through evolution, especially with humans where intelligence, the principal survival tool, is advancing. Fighting with windmills a la Don Quixote⁴ is still better than fighting with “no nothing.” Don Quixote, on horseback carrying innovated but outdated weapons of his grandfather, innovated as he could with his limited ingenuity, instead of a Spanish rapier of the period, at least knew who his opponent was.

The argument here is that every human activity is competitive. That means every activity should be supported by a viable action plan crafted strategically. This evokes the terms strategy and strategic with entirely different connotations in activity planning from the simplest to the most complex in a human system. While it is very difficult to identify and conclude the simplest activity in a human system, it can be easily appreciated that the job of a government is the most complex. It is governance. Following a format based on the actuality of the concept of national security leading to human well-being could lessen the complexity of governance.

Competition demands strategy. Strategy comes with stratagems. Stratagems contain tactics. Tactics is the competitive energy detonators that take the organisation towards the goal riding the strategy applying the feedbacks. Tactics spurts and supplies dynamic energy towards the goal, the end objective, in many short spells of time adapting to the deviations and remaining within the strategic premise of governance.

So what is strategy in a nutshell? Strategy is the long-term plan for winning with a competitive edge in an activity where the competition, in the absence of a target entity, could be with self for better result by performance in a human system. This will be further explained in this chapter. An active human system requires strategy crafted for every activity. In the absence of a strategy, an activity becomes productively vulnerable and devoid of purpose in spite of performance. For this purpose, it should make the objective of the activity strategic. It is important to understand that strategy, as mentioned in this study, is an activity element of a formal human system. It is not applicable to individuals or informal groups even if the terms are

⁴Don Quixote of La Mancha (Alonso Quijano) was the fictitious character created by the Spanish author Miguel de Cervantes in his satirical publication originally in Spanish as *El Ingenioso Hidalgo Don Quijote de la Mancha* (1605), first published by Francisco de Robles.

semantically apportioned in their activities. Strategy needs a formal human system to sustain it for different reasons. One of them is a lengthy span of time. Strategy is a long-distance drive—distance and time is important. This will be clear when tactics is defined at a later stage.

Strategy, therefore, is required for long-term objectives for a formal organisation or human system to achieve their definitive ends—goals. The formal organised human system at the shortest end of a communal chain is a family; at the longest, it points out the nation. It is more like a set of Russian Babushka or nesting dolls, with the small inside the big than a pyramid tapering to the top. National security strategy is for intervention aimed at its maximisation— NS_{\max} . The law of limitations continually clamoured by the law of invariance holds down aspirations in any human activity.

This is clear from the more familiar term used especially in corporate circles: strategic management and management strategy. Strategic management is an accepted and professionally thought-out and designed policy for managing the organisation or human system under competitive intervention. Management strategy is the crafted strategic plan of a strategically managed organisation to meet the end objective, the identified goal.

SNS and NSS are vital to be understood by all involved in national governance. That means the government and all associated with it. In the previous chapter, it has been concluded that it is time for national security governance of national human systems and further delay in executing the principles may not be advisable even though the human system is slowly moving to reach the level to accept such governance. Humans are not competent yet, but it is vital not to delay it further. In this attempt, it is important to those involved to understand and appreciate the difference between the terms strategic and strategy. It is not as easy as the semantics involved in it can complicate appreciation.

26.2 Strategy

So what is strategy? One of the oft-repeated questions that the author receives from inquisitive professionals and students in governance and management is about the perceptive meaning of strategy and tactics, and the difference between them. The questions may bear in different imports. But the answer to them is all encompassing and idyllically pronounced on winning the game irrespective of what the organisation or the human system stands for in its purposes and objectives. Strategy, therefore, is the leading factor that takes an activity or intervention towards accomplishment of an identified goal; tactics decide the activities required to do so.

Strategy weaves the activities and lays the complex trail to achievement of a governable human system. It is crafted. It is definable.

For this study, *strategy is the formalised and firmed up **plan of action** within a relatively **long** span of time, based on organisational **statements** and allowing for changes in its **execution** based on **feedbacks**, to achieve an identified and defined*

*end objective, meaning the **goal**, that will remain **singular** throughout the **intervention** once activated.*

The idea of strategy carries the following embedded dictums in its array of stratagems that a strategist should embellish while crafting and linking them in forming a strategy:

- Strategy is a **plan**, prepared according to the first function of management of an organisation.⁵ Hence, strategy is prepared by an organisation or a human system that is formal.
- Strategy is an **action** plan. Strategy is a plan for a determined activity with assured intervention from start to finish.
- Strategy is for **long term**. Long term is a relative expression based on the formal human system that is preparing the strategy. The span of time is based on the need of the organisation. Each strategy will require a natural period to complete, which will be the target time. Change in the time span will also call for alterations in the strategy and its execution.
- Strategy will reflect organisational or human system **statements**. Primarily they include the vision, mission, operations, social responsibility, sustainability and other statements declared in its various protocols and declarations. The complexity of statements of an organisation or human system will depend upon its size, stasis and the environment it is in.
- Strategy is **executable**. The plan should be practical for execution, not a desire or a wish however strong it may be.
- Strategy should be flexible to accept and adapt to **feedbacks**. Strategy in the process of execution as a long-term action plan should be flexible enough to accept, adapt and incorporate the feedbacks received.
- Strategy is to achieve a definite **goal**. There should be a well-defined and thought-out goal to execute a strategy. The goal has to be precise, identified and definite. The organisation should be determined to go for it. There will be separate strategy for different goals. To that extent, a goal will be the final or end objective that was determined to be achieved. An objective needs not be a goal, but every goal is an objective.
- Strategy will be based on a **singular** goal. It means every goal will require a definite and separate strategy.
- Strategy is **intervenable**. Strategy is executed by intervention between two end points in time. The end points need not be definite, but certain. This also means the goal is not likely to be aborted.

In this study, the explanation of strategy is framed and propounded to scholarly appraisal around the principles of national governance aimed at national security and doesn't cover any other strategy for governing any other organisation or formal

⁵The traditionally accepted (five) functions of management are planning, organising, directing, coordinating and controlling; or in some studies, they are mentioned as planning, organising, staffing, leading and controlling.

human system, large or small, but for the overall and overarching governing principles that are common for any strategy and all activities associated with it. The preliminary requirement for creating a strategy is that it should be based on a strategic concept of the organisation or human system. In this study, the organisation is the nation comprising the people identified with it. People are identified by the nation; nation is not identified by the people. Hence it is the people who have to care for the nation. Nation is their identity.

There is a common conviction that strategy involves uncertainty because it is a long-term plan, and, therefore, the active premise is future. It depends upon the understanding of future. Future is not strictly uncertainty. Chapter 4 exposes the term uncertainty appropriately for this study. It is a condition that one has to handle (to the best advantage) as much as possible while making a decision. In terms of decision-making, uncertainty is an element that needs to be transformed to certainty by elimination for the decisions to be clear and practical. Besides, uncertainty can override the time along with risk, competition, conflict and other decision conditions.

26.2.1 Origin and Appreciation of Strategy as a Term

It will help to understand the term strategy, before stepping further, by looking into its origin. The correctness of statements in this section can be questioned by scholars. Therefore readers' discretion and further inquiries into the theme are advised for conclusive analysis in any situation as it matters to past that too mired in legends and myths and the usual grapevine of history. Specific views of the author on strategy are expressed in the concluding part of the session. They will provide clarification to some of the aspects of strategy and its compassionate companion, tactics, to clear the air about intervention till the last push to the goal.

It is said the term is derived from the Greek word for generalship or leading an army, but it is also expressed that there is no record of the Greeks ever using the word. However, the military origin of the word strategy cannot be discounted as it is often heard in warfare along with tactics before it entered in mainstream communication on competitive organisational expletives depicting success—strategic that is. Military means the armed forces or the actions relating to them, especially in battle and war. The terms battle and war carry some meanings in the study of strategy. First, they are different. War is wholesome intervention in which human systems get engaged to defeat an identified enemy through battles. It is a game that involves among others competition, conflict, risk and uncertainty which demands strategy for deciding the intervention. War is fought through many battles.

The scholarly world has generally accepted that the first strategic propositions came during the period of Sun Tzu (544-496 BC).⁶ It is credited to the treatise *The Art of War* (*Master Sun's Military Methods*). Its origin is estimated to fifth-century BCE. The treatise is about land warfare as land was the only terrain humans had to negotiate in that period. The art of war is considered a classic in military strategy. Many other works on strategy followed *The Art of War* centuries later. If the treatise is counted as the start point for examining strategy as a military finding for competitive decision-making, there are also many military campaigns prior to that period that depicts strategic war fighting. The closest to them could be the Trojan War, which plausibly was based on true incidents epically transformed in storytelling mode (Chap. 9). Further, deep inwards into the gone time are the epic war narratives of *the Mahabharata* (before 500 BCE)⁷ and *Ramayana* (seventh-century BCE). *Ramayana* is considered older than *Mahabharata*. Both epics mention about exemplary military war strategies in multidimensional mode that defy time and terrain. But the over-encompassing fact remains that competitive approach in engagements starting in military formats and their applications which today the human system accepts as strategy.

The military aspect of strategy in the later periods has been highlighted in various literatures as well as scholarly research treatises such as the Byzantine literature (Greek literature of the Middle Ages) and professional textbooks on war and military. The Greek word “strategos” means military leader, a general and also a military governor in Byzantine Empire.⁸ It was the highest rank in the military or matter related to leading. It also means strategy is a top-down subject which is still followed in every human system. Strategy determines hierarchy or hierarchy authorises strategy and strategic decision-making. The top level in the organisational pyramid crafts strategy. The hole in the alleged Greek connection is that the researchers couldn't find the Greek using the term at all. For the Greek, it would have been “strategike episteme” or “strategon sophia” meaning general's knowledge and general's wisdom, respectively. This shows crafting strategy demands knowledge and wisdom, hence obviously meant for the top echelon of the organisation to decide on it, though authority doesn't mean wisdom. This is based on the conventional appreciation that the old knows better. Well, it doesn't mean the young should be discounted. They can be masters in strategy, but at the organisational level, the policy decisions stream from the top along the authority gradient.

⁶It is not clear whether Sun Tzu ever existed. There are sources that say *Sun Tzu* was born in the late *Spring and Autumn period* who became a general and strategist, serving king Helü of Wu. But the sources disagree on the birthplace. Certain degree of euhemerism surrounds the existence of the character as in many cases of yore.

⁷The Mahabharata war was said to have taken place in 3137 BCE. Kak, S. “The Mahabharata and the Sindhu-Sarasvati Tradition.” https://www.rarebooksocietyofindia.org/postDetail.php?id=196174216674_10151674678436675. Accessed 28 July 2020.

⁸The eastern Roman Empire after the split of Rome for administrative convenience into two parts: East and West on 11 May 330 (dissolved in 2 May 1453) under Constantinople and Rome, respectively. The official language in Byzantine was Greek and Latin.

The treatise with Greek title on strategy *Strategemata* by Sextus Julius Frontinus (c. 40–103), a Roman military commander, senator and author, literally weaves the idea of stratagems (*strategema*) which meant “tricks of war.” Another term originated from Rome was *strategia*, meaning territories under control of a *strategus* (not exactly *strategos*).

The meaning of the term strategy today is much more complex; it is still evolving. This study aims at amplifying the term leading to the explanation of strategy, tactics, strategic national security and national security strategy. This will require highlighting a few more past approaches on the topic, especially where it slipped out of the military jacket into other organisational frameworks such as corporate organisations and why such approach is necessary in the overall governance towards national security maximisation for peoples’ well-being.

French military commander Count Guibert (1743–1790)⁹ used the term “La stratégique” and explained strategy and tactics similar to the contemporary usage. Strategy till remained within the realm of the military before it started opening out into the business world in the 1960s. Competition in business started demanding strategic acuity in survival and continuity. One of the early proponents of corporate strategy was author Igor Ansoff.¹⁰

Strategy in national governance had a slightly different lineage running parallel with the military and subsequently corporate business. Kautilya’s *Arthasasthra* was all about strategy in national governance, appropriately called statecraft, according to the period. The treatise was estimated to have written around second-century BCE.

It took long down the winding time for other proponents of statecraft to appear. Niccolò Machiavelli (1469–1527) spearheaded others with his book *The Prince*.¹¹ Machiavellian principle can be roughly summed up as “end justifies means,” a reflection of the period. It shows how strategy is streamlined with the time it is originated. The end justifies means is not valid in an ethical environment which the present-day world believes though in minute parts. Achieving the end by any means is not appreciated today. It can encounter legal and ethical barriers en route. But the fact is that humans slowly became respectful to the other in spite of the survival pangs. The Machiavellian principles too were valid for the time. But these are aspects that could be carried home for the future. His classic, *The Prince*, to that extent was a kind of user’s guide where the user is the prince, the prospective ruler.

Many others followed. German author Adam Heinrich von Buelow (1752–1807), British Sir B. H. Liddell Hart (1895–1970) and the Prussian General Carl von Clausewitz (1780–1831) came out in the succeeding periods. While Buelow articulated the lines of communication, Hart was firm on “expanding torrent” theory. The torrent theory advocated diversionary attacks to keep enemy localised and a fast

attack by mobility to avoid confrontation with the enemy's frontline force in order to get to its centre of gravity—the command and control setup, and destroy it. Much later, this idea turned up as a short line theory in naval gun warfare stating, “Hit first, hit hard and continue hitting.” Continue hitting may not be necessary today if one can finish the other in one or limited go. The theory can be transformed to say “hit first and finish.” But there is another which says second strike is better. It is about hope. The second striker expects the adversary won't hit first even if the declared strategy is so over the fear of the second coming. This is projected in the doctrinal theories of nuclear warfare mostly as an excuse to hold the bomb or rather avoid the embarrassment of making it by subliminally stating “we made it any way, but won't use it” embarrassment. The world hasn't had a chance to turn the tables of Armageddon to prove the first and second strike strategies yet. It may never have the opportunity. If so what is the strategy behind the nukes? Excuses are not strategy. It also means every nation or nuke holder will have its own strategy under the universal strategic statement of deterrence.

In the backyard of nuclear time, much earlier, Clausewitz wanted to find answers to war and purpose. For him war was a duel of two minds and the one that is stronger and decisive wins. It makes sense as strategy is a mind game even at the corporate level. It is very much applicable in national security. One person at the top can change the course to rise or ruin. But in war Clausewitz' advise was strong and maximum force. The Chinese theories advocated soft and minimum force under deception and trickery. The duality is interesting. It says there is no need to what the opponent is doing. It can be even the extreme opposite strategies. But the issues in national security governance are much beyond wars and its theories. War and its purpose have changed in many ways since Clausewitz and so are the ideas of strategy. Wars are on its way out according to this study. Therefore theories of war too will slip away or dissolve in statecraft and governance for national security.

In the early days, military commanders understood there was no single strategy that would lead to victory. Military chronicles are replete with various teachings on strategy. That also shows strategy can be simple or unique. Every activity requires its own strategy based on multitudinous parameters for achieving identified goal. Obviously it is aimed at victory over appreciated adversary. Every strategy is different from another as situations and needs vary. So, one can say an activity will have its own strategic signature. It is this strategic signature one has to maintain throughout the intervention in spite of limitations as long as the goal remains the same, which normally will be at the core.

Russian author Leo Tolstoy ideated that man attains his greatest freedom in battle,¹² in his masterpiece “War and Peace,” a novel set against the background of the French invasion of Russia. A theory is acceptable if there is a certain degree of

¹²The author considers Tolstoy's ideation as one of the foremost truths, though it was not what he meant. The argument is “war gives the ultimate freedom to kill when killing is considered a wrong punishable in a human system.” It is much more than a licence to kill from an authority.

falsifiability¹³ in it. The question here is what is peace? War is understandable, and there are many theories on it. The world has witnessed wars periodically since thousands of years. It is clear. The search for peace takes one at the idea of war. But the idea of peace is mired in confusion like the idea of happiness. Peace projects a situation other-than-war. But what kind of an entity is peace? Peace is a situation “other-than-war,” whereas war is an activity. The title of Tolstoy’s classic has a mix-up. It could be better accepted today in strategic studies as “war and other-than-war” than the original where the terms are incompatible to each. But such a title is not comfortable for a novel. One is real and the other is an abstraction. War takes on to the wardrobe of Narnia¹⁴ which if opened will lead into a fantasy world. Meaning other-than-war situation could be worse and more complex because it will be riddled with unparalleled crime and conflicts and uncertainty. The fog and friction of other-than-war situation could be denser and more complex than war situation especially when demographic density increases along with ethnic aberrations and discords. It is certain. The natural stasis of human system, if there is something like that, can be one with intermittent wars and other-than-wars.

Does these statements ring a bell somewhere to understand strategy and associated tactics? One has to go deeper. The strategic formats may understand these lemmas. War and other-than-war certainly won’t sound well as the title of a novel especially in that time frame. Tolstoy was absolutely right on the title. It is only now an author is feebly challenging that the words (war and peace) do not match. One exists, one doesn’t. The theory can be argued to be true for the period when people thought of a situation, though imaginary, that wouldn’t cause pain and sufferings. Tolstoy’s premise of freedom is interceded by strategy.

Clausewitz was direct in advocating strategy.¹⁵ His strategic formats included maximising terrain advantage, surprise, multiple directional attacks, fortifications, assistance of the people and the use of great moral forces. These principles can be translated in national and corporate governance. But they are not sufficient or may be too short for many nations on the go. Among them *coup d’oeil* is author’s favourite. It works everywhere in strategic application—commanders insight, or the leaders insight. Kautilya too had mentioned some of them centuries before. Each one of them has its advantages and disadvantages as they depend on many factors. Similar or additional factors can also be identified by strategic decision-makers in relation to the decision problem in every field. There are others who identify levels of strategy such as technical, tactical, operational, theatre and grand. Ultimately it is left to the strategist and his or her thinking ability to unwind future successfully that matters.

¹³Based on Karl Poppers theory of falsifiability which says a theory that generates falsifiable conjectures can be said to be scientific. See Mukherjee, S. (2015). *The Laws of medicine: field notes from an uncertain science*. Ted Books. p.51

¹⁴In the Hollywood film *The Chronicles of Narnia: the Lion, the Witch and the Wardrobe* (2005).

¹⁵Carl von Clausewitz (1832) *von Kriege*. Graham, J.J. (Translator). (1873). *On War*, Vol.1–3. N. Tübner & Co.

Simply put there are no theories that one can follow as a standard for crafting as strategy in the times the world is in and will be.

An interesting aspect of strategy, again from the war scenario, is that of impossibility. The proverbial and motivational principle, “When things go tough, the tough gets going” is very apt in strategy. The inconsistency of a situation can be made use of by the more competent. The situational difficulty is favourable to those who feel it less difficult. A thief is good at night which is an unfavourable situation for the robbed. But the competitor for the thief is not just the prospective target, but another thief who may not be as comfortable in the darkness of the night and may prefer to use a torch. Paradoxical situations are catalytic to strategic intervention. A country can effectively use a pandemic situation to gain over another within the paradox by strategic application of governance.

Nuclear war strategy is mired in paradox. The nuclear weapon deterrence theory makes an expensive and secretive weapon acquisition and holding wasteful as the other party can also use it. Less advanced or successful weapons may remain useful when more advanced weapons proved ineffective against the adversary in military strategy. Less advanced weapons may find more effective and useful.

Uncertainty in strategy is a factor because strategy deals with the future. The very purpose of strategy is to clear the fog over uncertainty. Uncertainty as a limitation is a constraint. But according to the paradox theory mentioned above, it is this constraint that helps a keen strategist to overcome the enemy by just making use of it better than the other. It’s a kind of “the thief and the darkness theory.”

Strategy originated in the military against the background of war. Its use in other competitive fields of human system engagement such as business and governance had given sufficient boost to creative and constructive thinking. It is all the more important to the largest human system, the nation, in national governance. Strategic applications became decisive in shaping human systems in course of time.

26.2.2 *Tactics*

Tactics is part of strategy. But the terms confuse many. That is natural for learners of strategy. But the problem is when it prevails among practitioners, such as a corporate honcho or a minister in government. This statement is based on the type of questions the author receives. The answer is simple in the author’s expression: strategy and tactics are the long and short of it. But then what is “it” in this statement? The answer is “winning,” not victory. Victory is when strategy and tactics are used for winning, etc. Simply put, “it” is the gist of competition.

One of the objectives of an intervention process in governance is to prevent slowing down the activity unless it is part of strategy. There are many ways of slowing down that could be embedded in strategy. One of them is planned retreat in a battle. That itself is a tactics.

The term tactics also originated from Greek. It was *taktike* meaning arranging or ordering formations and arms for battle. This term got wider connotation in the

military vocabulary related to anything short—tactical weapons, tactical manoeuvre, tactical bombing, tactical sorties and so on. There are also other terms that are tactical sans the word tactical attached to the activity—surgical strike, drone attack, reconnaissance sorties and so on. The term when applied to other competitive activities may take a different hue, but the basic character will remain without alteration—the time span. The time span for a tactical activity as a part of a strategic activity will always be shorter than the strategic time requirement of the activity.

Governance is not war, though many experts compare governance, especially corporate governance, with war and use military terms in explaining various competitive activities. That can confuse real action required in corporate field. Using inappropriate terms can cause semantic dissonance. For example, guerilla marketing is different from guerilla warfare. Blitzkrieg actually means an overwhelming and swift offensive against the enemy using mechanised infantry formations. It is not applicable in governance of a nation or even in corporate governance. Therefore, such terms are not recommended in governance as they may deflect decisions. Semantic dissonance has no room in strategic decision-making. National security governance is neither similar to war nor about it. War is an entirely different human activity. It is within the national security. Application of strategy and tactics in business or governance cannot turn them into war or conflict. Strategic application is apropos competition, and tactical intervention is based on chosen strategy. As mentioned earlier, an entity may also compete with itself. Competing with self will be necessary for an organisation or human system either in the absence of an external adversary or when the adversary is weaker than itself. Every activity of a human system is competitive lest sustainability should slip away.

An organisation or a human system will not win over another by riding a strategy unless it is crafted and executed better than the competing strategy. Even then strategy supports the entity to move forward in its life process within sustainable limits. In other words, strategy can extend the lifespan of an organisation or a geopolitical entity comfortably. In geostrategy, containment of another country by an adversary falls within this principle. The country that is contained can still continue by clever strategy even if the opponent is strong. Execution of strategy takes energy from well thought-out manoeuvres at every stage on equally competent tactics. Ideally every human system has to function sustainably for survival. Tactical manoeuvres at each stage of strategic intervention support it. This comes only when sustainable development becomes the prime motive behind the activities of a human system. Competition and advancement by gaining bearing over the adversary are only part of it.

Some scholars believe that strategy is not necessary if there is no competition.¹⁶ Here they mean competition from similar systems. This author believes that for a human system to sustain, competition could be invoked from within all the time even if there is no external competition. This is more applicable to national security

¹⁶Ohmae, K. (1975). *The mind of a strategist: the art of Japanese business*. McGraw Hill Professional, 1982. p. 97.

because a nation expects to survive in perpetuity. The competition against self to keep improving needs to be compared with external if it exists. Normally it will. The tactical manoeuvres should be accordingly reframed along with feedback applications on the mainstream strategy. The secret of sustainable movement along time for a human system is to avoid the tipping point by all means. Decline can be held back, but beyond tipping point, it will collapse not decline. That is the reason for strategic planning for any human system in which the critical dynamics lie in tactics, the short steps that turned the stratagems perfectly well. It is not necessary that tactics should yield positive. The system may lose some. It should not be a cause for worry if the strategist knows how to plan the next move. Hence the saying, “One may lose a battle; it is the war one has to win ultimately.”

There are many definitions and explanations for tactics. For this study, tactics is defined as *the stratagems, the short term plans, that will lead to the goal identified and premised in planning, as part of the strategy crafted for it.*

26.2.3 *Strategy and Tactics: Difference*

Strategy is not tactics. They are complementary to each other, though. They are similar but for the span of execution. Tactics are executable and necessary components of strategy that operate as stratagems separately. Another way to appreciate the terms is that strategy and tactics are similar in design, but not in shape and execution. Both demands futuristic thinking. Strategy will comprise appropriate tactics to see it to the end in a relayed interventional format. If that is so, will tactics be always embedded in strategy or are there situations when tactics remain independent or isolated? This is not a difficult question to answer. Tactics is part of strategy like battle to war. There can be situations when tactics alone is felt or perceived in interventions without an amplified long-distant view of the end objective or goal. In such cases tactics, the short-term stratagem is actually a part of the long-term grand strategy, which the people involved are not visibly or perceptively aware of but carry out subliminally as a dogmatic and doctrinal behaviour in a human system. The grand strategy needs not be clearly perspective or crafted impeccably with a single focus. This can be seen in many human systems. One of them is religious human systems which are belief based. And belief is an individual prerogative exercised by groups in a human system. The humans behave individually within the religious group if it is a prayer even in company of others, but collectively in a conflict scenario. Every time somebody prays or shows aversion to god in the public or acts as a member of the group that believe in no god, he or she is engaged in the tactics that leads to the grand strategy of spreading or retaining or disapproving the other religion—belief system and the associated mindset that “my god can lick yours.”¹⁷

¹⁷Slang phrase used by the authors in the book *Critical Mass*. William E. Burrows and Robert Windrem. (1994). *Critical mass*. Simon and Schuster.

Yes, atheism is a religion from human behavioural aspects in this study and therefore not different from cultural religion or religious culture. Atheism believes in the god of “no god” and achieves the same security feeling that a religious person gets by belief in god and associated prayers and rituals. That also means human system that aspires for perpetuity functions subconsciously or consciously within a grand strategy and every tactics adopted to reach that may seemingly look as strategy or tactics in isolation. An academic differentiation of strategy and tactics is given in Table 26.1.

The differences between strategy and tactics mentioned here are for academic explanations only. They depend entirely on those who govern human systems. In the case of a nation, it will depend upon the governance and governing system thinking. As strategy is a top-down approach, it will also depend upon the individual guiding or governing from top and those at the various nodal points in the system that will fire tactics appropriate to the strategy.

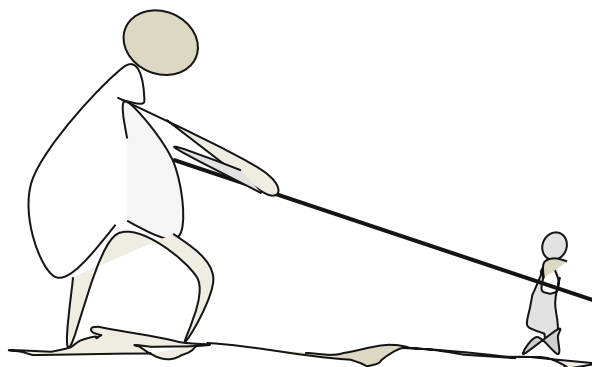

The ideas of the past masters of strategy are not really applicable in governing a state ultimately in the present and immediate future. The reality was different when the ideas were propagated, but for the overarching influence of the law of invariance. It was a mad, mad, mad world which it is still today. That is common. The governments know. The common traits about strategy and tactics then and now are both how a human system, the nation in this case, will achieve identified goals and objectives. It is a dynamic interaction with the passage of time over a human system. Tactics are crafted for tangible and specific action for slowly and sustainably moving strategy. Strategy can be felt when one goes through the tactical experience. Most of the people involved in tactical interventions will be who came much after the strategy started rolling. They will get the insight of it whenever they gain hands on tactical experience and apply feedbacks.

Similarly, among the differences, the long-term-short-term explanations are also not very holding. Strategy too can be short term but relatively long compared to the tactics applied in it. But a grand strategy, the strategy that ultimately leads to the grand finale of achievement, which is actually a never attainable target in a system whose half-life cannot be easily predicted, can be infinitesimally long. That is the ideal case for a nation. Hence national security strategies should be taken as long-term aspirations of continued well-being of the human system that makes the country. There are also cases where the tactics can outlive a strategy if there is a requirement of maintaining or holding the achieved strategy beyond its deadline. This is important for the topmost state in a global system to hold in that position. That’s why a formula for win-win or win-lost is easier than a win-hold-win or win-hold-lose in a game plan. The strategy to hold will require continued tactical displays even after strategy shift while the competition is on.

As an afterthought in teaching the difference between strategy and tactics, the author normally compares the terms in the mutual relationship between DNA and RNA in life sciences relative to genome (Chap. 23). In this comparison, if strategy can be compared with DNA, then tactics is RNA. Of course not exactly, since DNA and RNA are not strategic and hence tactical companions of survival of life (Box 26.2).

Table 26.1 Difference between strategy and tactics

	Strategy	Tactics
1	Thoughtfully crafted long-term plan of an organisation or human system relayed over many well thought-out tactics into the future for achieving an identified goal. Long time frame	Well thought-out short-term plans for conversion into interventional activities that take the strategy towards the identified goal. Short time frame
2	Long time frame. Sometimes the entire lifespan of the human system or organisation	Short time frame. Within the duration of the relayed responded time for each tactics to complete and hand over
3	Based on extensive brainstorming, research, internal reflections and intuitive thinking in how to think mode	Based on brainstorming and productive thinking with the organisational strategy as the single point of focus and aligning with it
4	Strategy originates from top level with or without contribution from the bottom	Originates from the middle with or without contribution from the top and bottom
5	Highly competitive in nature therefore very proactive and highly monitored and watched over	Highly reactive nature and therefore executed from start to finish without interruption in each tactical situation
6	Limited flexibility	Highly flexible to the extent a tactics can also fail at times
7	Corrected through feedbacks	Corrected immediately
8	Orientation to the long and distant future	Oriented to present and immediate future
9	Based on achieving competitive sustainability	Based on competitive intervention
10	Focus on resource generation, organisation and effective distribution	Focus on effective resource exploitation
11	Organisation specific	Organisational strategy specific
12	Vast and well laid-out expansive plan that covers the entire aspect of the overall end objective—the goal	Short scale plans for action in small steps, each leading towards the strategic goal through identified interim objectives
13	Independent aimed at an end objective, the goal	Part of a strategy aimed at the strategic goal
14	Singular	Multiple tasks executed simultaneously or singularly
15	Permanent in relation to the goal. Only altered by feedbacks without losing focus on original goal	Temporary till execution and completion in a span of time. Tactical interventions may fail, continued and changed in course of intervention
16	Crafted and planned in five steps according to organisational goal based on vision and mission statements under strategic governance principles	Crafted and planned as tasks an activities according to organisational strategy under strategic governance principles
17	Continuous	Relayed. There can be interruptions
18	Strategy works with tactics for support to attain the end objective.	Tactics work with strategy in support of o it in short steps
19	Strategy gives rise to tactics	Tactics aids strategy
20	Overall campaign plan	Actual means to reach the goal
21	Always come first; set before tactics	Always come after strategy

(Drawing: Author)¹⁸

Fig. 26.1 Strategy and tactic(s): Identical but different. (Drawing: Author). (The march was also known as the Salt Satyagraha. The 390-kilometre Dandi March and the associated Dandi Satyagraha were an act of non-violent civil disobedience movement in colonial India led by Mohan Das Karamchand Gandhi. The march commenced from Sabarmati Ashram in Ahmadabad on 12 March 1930 and ended at Dandi (Navasari) on 6 April 1930, where he broke the British monopoly on salt and the salt laws at 6:30 in the morning. That earmarked the beginning of the non-violent civil disobedience movement in India against the colonial British)

Box 26.2: Strategy and Tactics: The DNA and RNA of Competition

Nucleotides are the basics of both DNA and RNA. Both strategy and tactics comprise stratagems. DNA provides the code for the cell's activities; strategy provides the course for governance activities towards the goal. RNA converts that code of DNA into proteins to carry out cellular functions. Tactics converts the course in small incremental steps towards the success of strategy in continuing governmental functions. Does this make a difference in appreciation that both are similar but different?

For the still inquisitive strategy and tactics are identical twins. The one that came first was strategy and the other is the supporting twin who came seconds later. Tactics is a dwarf, but very powerful and leads strategy to winning (Box 26.3 with Fig. 26.1).

Box 26.3: Gandhi and the Leading Kid at the End of the Stick

The picture that comes into the mind of the author is that of Gandhi walking with the help of his grandson (Kanu Gandhi) leading him holding the other end of his long walking stick during the famous Salt March (12 March–6 April 1930) to protest against the colonial decision of raising tax for salt. Gandhi is the all-pervading strategy and the kid at the other end is tactic.

26.3 Strategic National Security: Continuum Approach

Strategic national security ideally is the strategy a nation has to adopt at the time of its “birth” which is the quantum beginning time of the defined human system and is only subject to change when the nation is not in any way identical to what it was before. This concept applies to the state of the nation even before the sovereignty concept came up. The nation in national security statement is the nation that serves as a continuum of human existence in the form of unified system even if the opinions within varied. This continuum is important in strategising national security. This method overlooks the social practice of macro- and micro-level studies to understand the continuum position of a human system as a nation that is governable and thereby governed. A “nation,” whichever way it was, loses its continuity when its original characteristics are totally lost and acquires a different format. Sometimes the name may change or may retain the old name in the new format. Or the nation may totally vanish from the maps as a nation even if name is retained. There are many such nations, and this study refrains from naming them without further research and debate in right earnest. Besides, it is not necessary to discuss about any nation specifically in the present context. This study respects every nation as a unique entity.

The people of a nation should be aware where they are in the continuum of that nation for crafting strategic national security. Quantum beginning of a nation throws light on its vision and mission for declaration to guide along the path of governance in its remaining lifespan as a continuum. Strategic national security appreciation will change only when the continuum factor of that nation is broken even if it retains the previous name. It is applicable to all human systems. For a nation, the continuum will break only when there is total change and absolute transformation. It doesn't get broken under circumstances such as colonisation, coup d'état, rebellion, independence, change of government, etc. in the usual case of course alteration or change. It continues as the same nation following its continuum track regardless of changes in the momentum. The continuum changes for other reasons for which one has to understand the lifespan of a nation. It will be known to all when a nation ends and alters into another or when a new nation is born *ab initio* or vanished forever. Anything that comes up in its place could be a new continuum start-up.

The lifespan of a nation is similar to the lifespan of any human system including families and corporations that reflects the lifespans of humans. But a nation is not similar to an individual human. An individual human cannot take shape into another human after his or her death. But a nation can, and it usually happens in most cases, though afresh. Similar to an individual human or a corporate or other organisation, a nation too shows four main stages of life—birth, growth, decline and death. There are various other stages interconnected within these stages. They are not mentioned here. The lifespan is a continuum which for governance is taken in perpetuity though it may not be possible as the law of invariance shows. No government governs its nation as if it is going to end one day. But it will. Only the time span in existence may change for nations. The continuum breaks when the nation dies. This continuum is

important in strategising national security for governance. But it won't be known. Though within every nation and external to it, there will be forces against its continuum lifespan. Most of the efforts of governments go into activities from preventing the end of their nations. The terms they may use is breaking off or breaking up. This takes away a lot of strategic yield from governance towards the well-being of humans. It is similar to physical friction that induces inertia. But many nations can withstand it by its inherent capacity which is expressed in many ways: soft power, inherent power, traditional value systems and so on. But according to the author, sustenance of the nation as previous in a continuum format as long as possible adds great strength to a nation which helps governments in governance and also prevents the governments themselves from going against it. This can be observed in nations of the world independently. According to this theory, there is a paradigm statement: "the longer a nation can survive as a continuum, the longer it should survive as a continuum or the harder it will be to break completely". Well, this statement at the moment remains an untested hypothesis.

Many things do happen to a nation in its lifespan of the four critical phases. Smaller organisations too pass through these phases. Students and scholars of organisational theory and process will be aware of it. A nation is also an organisation which the author calls a meta-organisation where the theories of smaller organisations such as corporates, etc. may not apply directly. The lifespan of a nation covers all the four phases. Some of the phases can be extremely short or vacillating. For example, for a nation that dies in a short span, the growth and decline phases will be short. This is for academic understanding. The lifespan time is what a nation should ideally declare for governance. That means the vision and mission that a nation should follow throughout are the survival continuum in its ideal sense. It reflects normally in the constitution of the nation. But situational change subsequently may demand changes in the vision and mission until the course alters. If the nation is permanently interrupted in governance like most of the nations in the world, it may require a new constitution or a new vision. The continuity of a nation is important for this. If national security is aimed at well-being, then governance should be strategised to keep the continuum factor going perpetually. So, national security remains continuously as an ongoing programme for a government acceptable to all governments that will fall in the continuum path. This is strategic national security.

Crafting strategic national security calls for various steps. In the beginning, it will be necessary to understand when it all began, what all transformation has taken place so far, whether it is growing or declining and more than all the exact positions where the nation is at the moment unaware where it is heading to. A nation is dynamically in motion. Thereafter the governance focuses on strategising further plan to turn around the nation if it was declining or enhance the momentum if growing. Further the nation should know how long it wants to survive the way it is making headway or any change is required. It will demand competition, and strategising national security is to meet this competition which also includes with itself.

Normally, a nation by virtue of its formation is there to take care of certain group of people. That is why nations are different. There will be difference of opinions even among these people once the nation is formed based on the binary axes

compatibility. Hence, ideally all nations need strategic national security approach to overcome frictional losses by fighting against constraints that have no forward yield but prevention of breaking up. Governments spend lots of effort in preventing such breakup. Even otherwise momentum may not be easy for various reasons:

1. There can be requirements to perfect strategising national security. This will call for amendments based on feedbacks.
2. Need to change what the previous governments have done. Normally this will include minor changes by course alterations.
3. Change by permanent interruption (death of the system) where the course is widely altered as in micronisation or macronisation or a change in national attributes like a faith system-based change.
4. A change from anarchy to agent-based governance (democracy).
5. Changes within when the axial influence changes.
6. Formations based on international law such as supranational formation.
7. Other situations (research required).

The bottom line is that a people and its government should be aware where their nation stands along the continuum path and decide and format the vision and mission for the nation in governmental intervention.

26.3.1 Vision, Mission and Intervention

A vision is the determined and pragmatic future that a government or the country likes to acquire through national governance which ideally is based on national security leading to well-being of people. The principle on which a vision is made is based on the continuum paradigm as no government or people would like to envisage their nation ending up dead, and like to believe it will never end. Under such premise the vision is to govern the nation successfully towards development and sustainability to provide maximum well-being its people. It means governing by national security (GBNS) with the outward intention of keeping the continuum going perpetually forward which also means elevating the nation's inherent strength to avoid disruption and breakup that may lead to the end. Under this premise, the vision could be for what this study calls continuum governance. Continuum governance ensures longevity and thereby continuity. The vision statement has to be written to include continuum factor and well-being of people the way the government appreciates them. This is under the presumption that no government or people will govern their country with intent to destroy their country permanently to start afresh in a new frame of continuum.

The mission deals with the pragmatic procedures and activities for executing the vision. The action plan will be specified with critical appreciation. The critical factors to achieve the vision will be specified in the mission statement. The mission should be logically connected to the vision.

Vision and mission statements are essential for strategising national security for GBNS. They deal with the future and are declared in a forward thinking mode. The futuristic appreciation should be ever visible in the vision and mission statements and brought out frequently by governments in action.

Intervention in governance is similar to operations though government will execute its plan according to the constitution and appropriate policies. Government intervention to that extent is any action carried out by the government or associated authorities in the elements of national security integrating them as well as the terrains where national security is governed with the direct objective of maximising human well-being. National security strategy that originates from strategic national security is essential for governance interventions.

26.4 National Security Strategy

National security strategy is the strategy a government may craft for executing strategic national security envisioned and expressed in mission statements. National security strategy has to be crafted by the government. It may differ when governments change though ideally it should match for the continuum future. In this context, national security is considered as the wholesome concept of human well-being, whereas it is yet to achieve the wholesomeness as envisaged here.

National security concept in almost all nations still revolves around the archival and archetypal physical security and associated econo-political concept of the military. Even in the United States where the concept was originally viewed beyond the military, national security strategy (NSS) is a report mandated by the Goldwater-Nichols Department of Defense Reorganisation Act, 1986 (Public Law 99-433) every year. The president of the United States sends it to the Congress in order to communicate the executive branch's national security vision to the legislative branch. It has to be a document permanent more or less in status with the constitution based on which any reports can be made for any given period. The case in other countries is also no different. Every nation follows the concept as expressed and conceived by the government. It can be a political battleground for the government in governance. India faces the wrath of breach in physical security termed by the politicians and media as national security not only over the ground but also in the Parliament quite frequently. The critics who comments that a holistic discussion of national security rarely occurs in the public space also means aggressive activities of the aliens thereby pointing at the military security which in reality is only one of the elements of national security. This old archival idea of national security that still lingers on in the mindsets of the public and their representatives besides the media, the fourth column or estate, still creates major issues during elections and in between slack periods causing frequent traffic jams in the overall national security.

India has plenty of such issues, that become fodders for the opposition to belch and protest and other systems to play around, including terrorism, insurgency, cross-border incidents, ingressions of crimes³⁺, spectacles of violence and so on. Similar

issues are there in many other countries. The engaged governments should understand that national security strategy covers the interventions of government related to the interventions in the 16 elements in 8 terrains as specified and anything else is action demanding under conditions including rule of law. The opposition in government and the informers to the public, the media, too should know and invoke the necessary strategic silence for security of information. They too are partners in SNS and NSS. It is a national requirement. Crafting a national security strategy according to its modern wholesome concept has to follow a comprehensive approach encompassing all the elements of national security and the factors of integration in all the relevant terrains highlighting the interlinkages and required alignments. It is a major task with internecine feedback loops and coherent templates for multi-modal government interventions during the period of the government and beyond for other governments to follow. National security strategy should be continuum bound and not meant for a single government to use during the period it is in authority. These are idealistic statements that may not work in most of the countries as governance often shifts and strategic planning of national security changes. Such situations will seriously impair the overall national security strategy. Worse is when a country doesn't have a defined strategic national security. The national security strategy takes the essence of strategic national security for interventions. The ultimate losers in any case of human system governance will be member stakeholders—the people.

Crafting a national security strategy is the most critical aspect on the schema of governance for any government. It is not a run of the mill aspect. For many, it is like driving on an open field without a road. They may craft NSS; it could be based on their own definitions of national security. They may or may not have a serious SNS appreciation. No nation today including those who claim to be on top have a formal national security strategy aimed at point blank well-being of the people (2020). Another mistake countries make is that they may have one for the go for the government that is never changed throughout like sleeping on the same bed without changing covers. Worst is when the next set of government makes their own NSS as proof that both the governments don't know what national security means. This exercise goes on like an amusement or observation wheel in the park. By calling a bundle of papers with interspersed words that sound strategic doesn't make it a strategic plan. It is worst in electoral democracies where the opposition won't even allow a government to go comfortably a vaccination programme in a pandemic or support the aggressor publically in war without allowing the cadres to support own country. Human systems are still in the pit where they were born in the beginning. If human advancement is required to be regulated so sternly by nature through law of invariance, it is not likely they will get out of the inertia of survival emotions even in a time that equals the time they spent so far. Frankly, this can be assessed. That is the reason why governmental systems have to change by those in the forefront of sapient system in the unitary civilisation worm train by not devolving or going backward but stretching out in the evolution. That is when strategy takes shape. The prime competition in a human system is with self.

The core objective of national security strategy for all governments should be ideally common in a continuum. If not, it means the end objective of national

security is vacillating and is not identical. That is why the constitution in whichever form it may be is critical for SNS for a nation as the fulcrum. Nations that die get recycled in another form with *ab initio* continuum unlike other life forms. Yes, a nation is a life form for this study. They rebuild in another form.

The constitution holds the key. The national security governance ideally follows the constitutional path. But it changes when the continuum breaks. National security, if universally accepted as a concept, should remain the same. Only the process of governance should change. All governance should lead to human well-being not only local but also the global human system because governance should cross the system boundary. In that case, national security concept is ideal. The changes are on the approaches. Any approach is acceptable if the destination is unchanged. Crafting the strategy is for the approaches not for the goal if the concept of cross-border human well-being is accepted universally. It also means it is not the type of government but the end objective that matters.

26.5 Steps in Strategy

Strategy is essential in competitive situations. They are long-term plans for winning a situation. There are various theories that advocate the steps that need to be taken in developing strategy for a particular competitive requirement. Most of the theories are basically based on smaller systems such as corporates and even for nations in specialised fields of specific national interests. Strategic national security and national security strategy will require macro-level thinking on matters related to national governance according to the constitution of the nation and policies envisaged by the government within its limitations. The steps, therefore, can be standard provided each nation has a common objective—national security. But the nature of strategic planning will differ from country to country depending on the concept of national security perceived by each.

The strategy a nation has to adopt relates to two different scenarios: (1) SNS and (2) NSS. SNS is the basic requirement for NSS. A government needs to identify SNS before it decides to craft the NSS. The continuum status of the country can guide the government to decide on its strengthening national security based on the Constitution of the country. The constitution whether written or otherwise is a handy instrument that guides the vision and mission statements, or in general, what a country should look for in its movement forward. It is a kind of user's manual. The continuum factor—where does the nation stand in its continuum passage—is a key element. The longer the continuum, the more intricate it is for understanding the turn of events that may impact on sustainability because the country would have gone through lot of complexities in its long existence like the battle weary soldier in a prolonged war. The country would have sustained many injuries in its long drawn-out existence to maintain the continuum sustainability. Long drawn-out battles for sustainability can take its toll while identifying SNS and thereafter the NSS. But there are advantages also. The longer the continuum, the country will be with

accumulated experience, knowledge, wisdom and tolerance. This should compensate for the battle weariness with determination, experience, confidence and knowledge. The country will be seasoned and optimistic but could also be obstinately complacent. Most of the people may not be even aware of the strength of their nations, especially those who are critical of it based on their perception of survival. In all situations of judgment, one has to see the nation separate from its people and then decide on the resultant effect of the nation and people together. It is important for decision-making on SNS and NSS.

The countries that are long continuum states will already have SNS conceptions based on its conditioned past. The countries that have just started their fresh continuum journey will have to start anew or modify the existing drastically. The NSS thereafter is established based on the SNS in various steps that the government finds acceptable. It will include the standard steps in strategy creation and execution through feedbacks. A nation without an identified strategic national security in its governance format may find it difficult to craft national security strategy.

26.6 Measuring Strategic Yield

Measuring the progress of strategic interventions is necessary to understand how close the system moved towards the identified goal since the interventions initiated. The yield needs to be checked continuously to appreciate the progress of intervention, whether ahead or behind the target with respect to time. This is required to change tactics appropriate to move up or down as the organisation desires. This will also help in deciding whether the tactics need to be changed or honed for better results.

Effectiveness and efficiency are the two key assessments in this process. Effectiveness is the *sufficiency of intervention to accomplish a purpose. The yield is effective if the intervention produced the expected result. The yield is efficient to the extent it is acceptable with respect to the input. It is the ratio of the output with the input or resources spent. It is the performance ratio of the “end” with respect to “means.” The yield with respect to time when compared with the desired result will explain the effectiveness and efficiency of the strategic intervention. Decline in effectiveness or efficiency needs not be a cause of concern if it has not affected the competitive concerns in the strategic process. On the other hand, it will be a concern if the system governance has lost bearing relative to the competition. Performing or functioning in the best possible manner minimising time and effort is a measure of efficiency.* A strategy is effective if it delivers the expected results relative to time with the allocated resources. It is efficient if the competitive output is as expected or exceeding the expectation. That is why one has to appraise strategy with respect to the goal, whereas tactical appraisal is with respect to strategy it represents, as a battle to war.

A strategic intervention may face the following four different situations in the effectiveness-efficiency matrix:

1. Effective and efficient.
2. Effective but inefficient.
3. Ineffective but efficient.
4. Ineffective and inefficient.

Generally, it is said effectiveness is doing right things and efficiency is doing them right. This is only a passing remark to appreciate the difference between effectiveness and efficiency. They are different in actual situation on the ground.

Strategic interventions need to be monitored and tracked to understand through metrics to appreciate the status of the yield and thereby success periodically. The metrics will include key performance indicators (KPI) and measures that will track the interventions and their yield at different intervals to assess the progress. Key performance indicators are quantifiable measurements of performance and achievements leading to the end objective in comparison with the competitive target. The KPI uses quantifiable data that can be used to decide further plan of action in the strategic intervention.

Similarly, it is important to measure the tactics adopted for their performance yield because they will lead to strategic effectiveness and efficiency. Tactics are short-term stratagems hence will have a time frame that can be visualised while they are on. The milestones can be marked more definitively. That means the resources—time, funds, materials, personnel, etc.—are directly measureable, and the expected yield can be appreciated before the move itself sans the issues that may come up during the process.

26.7 Strategic Role of Government

Ultimately, it is the state that is more powerful than any other human system power. The state can subdue all other powers within the system. The states get defeated only on the military and economic power of others that too if the government indulges in power abuse. Authorities in power can abuse their power. The worst scenario of power abuse is helping another nation at the cost of one's own country. Unfortunately, humans become weak and senseless when selfishness strikes. They may succumb to pressure and turn self and system destructive. Some compare it with selling the mother in the slave market. According to the author, the worst form of power abuse in a government is selling or giving away the sovereignty of a nation and its exclusiveness as a continuum nation including the land and borders without the knowledge of the people, to another and engaging in Crimes³⁺ for fringe benefits of different kinds all leading to political and self survival. Power abuse is a survival track for those who are not confident or framed in perceived security to gather apparent security. That is why the argument that a nation is different from its people. A nation cannot self-defeat, but its people can, especially those in authority. That is why it is generally said that for any nation, the threat is from within. A government whose authorities do not submit to vested trade-offs is on the other side of national

governance as ideal government of responsible population. In between are indifferent governments of convenience. The population may see all types of governments in their own country and also around.

Power abuse is a human personality trait. The electoral types are in no way different from other types of governments in power abuse. From the point of power abuse, this similarity is one of the test proofs that makes the author call all governmental systems as democracies (where people rule through an agent—government). It is difficult to make a human free from power abuse because of the dominant survival belief systems and auto responses. But it is possible to keep a government that can refrain from the urge to power abuse. Anarchy being the other form is a track to hell and destruction in the long run. Being on the decline slope, the strategy required is only to turn around. If anarchy continues, the continuity may come to an abrupt end—sudden death. Every government or nation drifts to anarchic state at the telomere end of decline in its lifespan.

A government has many roles. The roles are decided by the concerned government. Some are common; some are specific to the government; some are specific to the nation. In one of its roles, a government works like a corporate organisation making money, spending and keeping it as reserves and surpluses for further financial and monetary, and overall economic development of the nation. In another, it raises funds through taxes and fees and controls the economy. All are matters of governance. But economics is not all that a government does. There are various other roles also. This can be seen if one looks at the elements of national security which is a defined term that can further define the role of government. Everything associated with the definition includes the role of the government. It means the role in principle is maximising national security. Any maximisation process is competitive, and anything competitive is strategic. The role of government is strategic. It is important for people to know.

In performing the strategic role, a government will have to strategically optimise the elements and integrate the terrains towards NS_{\max} .

26.8 Strategic Integration of Elements

The need for integration of elements for maximising national security comes from the fact that each element is mutually inclusive. Involvement in one has an effect on the other. The overall trade-off has to be balanced or made positive. Integrating the elements with respect to national security strategy for balancing the elements or turning the output positive is necessary for maximising national security, otherwise the gain in one will be offset by the loss in another. The elements, therefore, need to be optimised in GBNS.

Integrating elements of national security is a tedious task. It requires identification of elements appropriate to a situation specific to the country. This is a difficult task when nations have different perceptions of national security concept. This also means copying or following the wake of another nation will not be appropriate. It

can ground the follower. Inclusiveness or inter-dependability of an element (Cannot Stand Alone—Chap. 6) with other elements is one of the characteristics for identifying an element of national security. A nation may not have to bring all the identified elements in the strategic appreciation of its governance problem. The process of integration of elements has to be developed strategically. Obviously, each government will have its own process plans.

National governance, generally, is a meso-level concept in the study of national security.¹⁸ It seldom reaches the macro-level or goes to the precision of the micro-level. The macro- and micro-level concepts also change within the federal system. The majority governance formats are at the meso-level. The sustainable development goals (SDGs), for example, require meso-level governance for a nation with federal or state participation in the global context. It may look complex, but an integrated policy can help to stream the process in a phased manner through the programme period as part of NSS integrated with the elements.

26.9 Strategic Integration of Terrains

The next step is integrating terrains with the national security strategy. National security is not a terrain remote concept. The grave mistake a government can make in GBNS is treating them exclusively. This is most visible in integrating the ocean. Ocean by its sheer expansiveness makes humans consider it as something exclusive without knowing it is similar to any other water body over land with specific characteristics. Even the coastland and island nations perceive the oceans separate. This could happen with other terrains too. Such appreciation will reduce the yield in the overall national security maximisation process. There are 44 landlocked countries according to a study by the author in 2008.¹⁹ All the landlocked countries are also maritime countries according to this study as they are benefitted or impacted by the ocean one way or the other. The explanation on ocean is to highlight the importance of terrain specificity of national security governance. It applies to all the identified terrains, and therefore they need to be integrated in national security governance as per the strategic national security vision of the government.

¹⁸The macro-, meso- and micro-levels are the layers the sociologists find convenient to define and understand social behaviour and interactive connections or linkages in a society. The micro-level is the smallest and most precise where individual, families and small groups are examined. The macro-level is large system, whereas the meso-level is the in between. The author recommends to retain governance at the meso-level integrating elements though ultimately the results will percolate naturally to the micro-level where individual well-being is the desired end objective.

¹⁹Paleri, P. (2009). *Coast guards of the world and emerging maritime threats*. Ocean Policy Research Foundation. p. 48.

26.10 Strategic Integration of Elements and Terrains

Strategic national security is based on the vision and mission statements of a nation formatted according to the principles of the constitution of the land. Therefore it is imperative that the elements and terrains on which the elements act are appropriated by integration in the NSS, whereas the changes in the SNS need not be that frequent unless the vision and accordingly the mission are altered subsequent to a breach in the continuum position of the nation. The continuum phase of the altered entity starts afresh from that point.

Integrating the elements and terrains jointly in governance is different from integrating elements and terrains separately for national security. The strategy for such integration needs to be crafted. The process is integrating the integrated elements and terrains together for framing the final strategic plan. This again depends on the national policies and acuity of governance of each government. There are no standard formats for crafting strategy being situational and depended on the continuum position of the nation and the environment through which the nation is moving. An example is planning an element-terrain integrated national security strategy when the nation is under the grip of a containment policy of a more powerful nation or a group of nations. The victim nation can do a lot in such case if it follows the continuum appreciation and assess its national security environment to avoid a total collapse in the distant or not too distant future.

26.11 Why Strategies Fail?

Strategy has been mentioned many times in this book though an exclusive study has not been carried out. This is not a study on strategy. Strategy is the accompanying actor in decision-making in GBNS. Strategy is always associated with tactics. They don't function or exist in isolation.

Governance is also about behaviour modification of the people for the better. It is an act. It is associated with everything humans do. So naturally they are subject to the law of invariance and the law of limitations within the principles of human singularity and differentiability. In spite of all the care and understanding, strategies do fail and governments either collapse in their performances or cave in and vanish. Nations too become non-existent as previous. Some of the interregnums reformat nations into totally different continuums. History is replete with such interruptions in the lives of nations that are vanquished and vanished. Such criticalities of existence can continue, and many nations of the day need not be there tomorrow. But their land will remain unless sea level increases. That too has a limit.

People may quote strategic failures of governance in all these. But the author believes it is in the natural life cycle of nations which changes according to the forces that play with human systems through, yes, embedded governance. In other words, it is governance of the time and period that stretches or snaps the continuum. That

means continuum governance is the key. It also means continuum governance is GBNS which emphasises human well-being which in turn leads to sustainability, which is nothing but the much mentioned continuum in this study. Governance requires application strategy in the format of SNS and NSS. Failure in governance is generally absence or failure of strategy along with other leading causes.

There are many reasons why strategies fail. Some of them are mentioned below.

- What the government thought as strategy was not strategy—misconception.
- The strategies concluded for intervention were not totally and pragmatically implementable—wrong premising.
- The good strategies were marred by wrong tactics—tactical incompatibility.
- Span of national governance was short—time deficit. This happens often in politics. This is what certain governments try to overcome by insisting longer period for governance for a government or individuals at the helm.
- There was serious semantic dissonance in strategic applications. Every term used in strategic plans should be definable and appreciable to all involved in intervention. Misleading terms such as string of pearls, blue ocean, blue economy, coastal security, climate change, global warming, China syndrome, Indo-pacific, West Asia, rim countries, coalition, sea denial, space pollution, and so on are good to use in geostrategic fashion statements and media terminologies but not in SNS and NSS designs. Caution is advised even if used in specific narratives.
- Lack of clarity in vision and mission statements that are frequently changing or non-existent.
- Velocity of flow of money and funds for strategy implementation.
- Mismanagement of weapons and military.
- Debt—domestic and international.
- Errors in planning and mistakes in implementation.
- Absence of feedbacks and casual approach to received feedbacks.
- Competitive disadvantage.
- Internal issues and professional incompetence.
- External involvement in war and conflicts.
- External involvement in covert actions.
- Power abuse.
- Misconception of strategy from what it is not.
- Wrong targeting—primary aim is to keep the government in place or win the next election.

26.12 Summation

Strategy is a long-term plan to win against an identified entity that is directly or indirectly in competition with the objective that the strategist wants to achieve. The objective normally is at the end as the end objective, also called a goal to distinguish with the intermediary objectives that act as tactical objectives assisting the forward

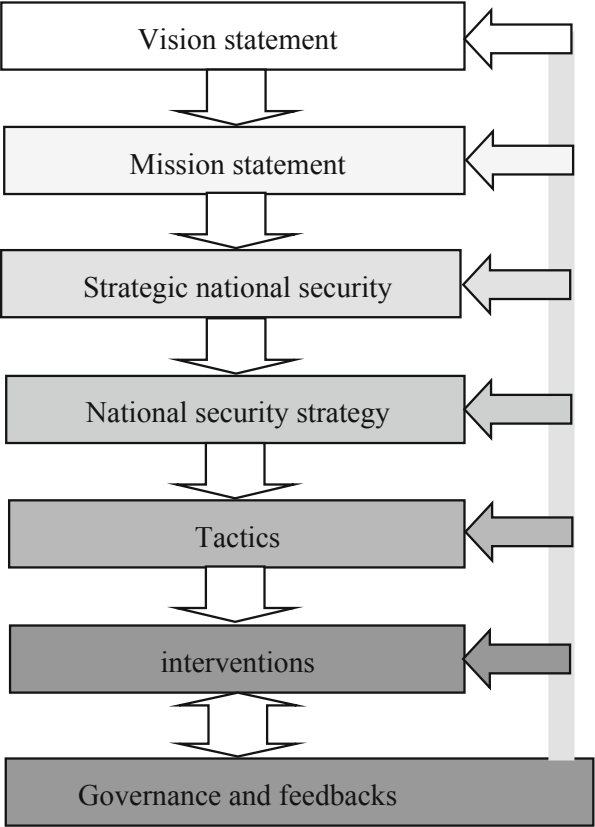

interventions to achieve the strategic goal. The strategic goal can be just one towards the end as a firm and fixed goal post or a moving target that cannot be reached in which case moving towards it directly or maximising it becomes the objective. In all these assessments, the objectives or the goal are not mere wish lists or desired goalposts but identified and determined pragmatic targets of governance. The goal of governance in this case is national security maximisation towards the well-being of the people.

The objective and the end goal should be clear to the nation and its governments. The process of governance should be accordingly determined as preferable to the government. In the conceptual case of national security, every nation will have the same goal at the end—human well-being—but the process of going towards it will vary. It will be based on the crafted strategy. The governments will do good to craft their strategies based on the characteristics of the nation including its continuum stasis among the nations. A nation therefore can be governed for maximising the well-being of the people only by those who understand the nation and its people. They need to have strategy crafted competitively for achieving it. This will determine the results and the national security index, the comparative appraisal index of well-being of a nation.

The nation should be able to decide on the strategic national security before crafting the national security strategy. Strategic national security is a policy of the government as a plan. The premising and targeting the requirements of governance need the decision that the nation will approach the problems of governance strategically. Most of the nations may not have a strategic national security policy. Such nations may find it difficult to strategically intervene in governance even if it decides on national security strategies. Such strategies cannot stand on firm commitments that the changing governments can follow. Normally governments are seen following their strategies sans a determined policy on a definite and long-standing national security strategy. This will make the action plans of one government null and void when a new government in any format or type takes over. It also means loss of time and cost in competition within the global system of governments. This is where the nations may also feel the deficiency in their vision and mission statements. This shows how governments fail. This has been mentioned briefly in the section why strategies fail.

So ultimately the process of strategising national security for governance and subsequent interventions in governance is similar to any human system, but for a nation it is macro-level engagement. A diagrammatic representation of the steps and process involved is given in Fig. 26.2. In this diagram, the steps are shown from the vision statements to governance through intervention, and feedback is to the entire steps compounded as well as individual. The diagram is only a schematic representation, but in actuality, it will reflect the choice of government and style of governance based on each type of government. This is not applicable to the anarchic form of governance.

27.1 Introduction

“Can there be tradeoffs in national security governance; if so, can it be quantified?”

This is an interesting question the author may pose to all those who have read so far though the way this book is written is in “read anywhere style.”¹ It also takes the line of the opening quote that a human can actually bargain, or rather had bargained more

¹Meaning the book can be opened anywhere and read from there in staccato fashion. This makes each chapter independent of the other for reading on the run or pointed research to some extent (see preface).

or less everything, except own life, as read through myth, legend and history (MLH) (Box 27.1) so far. A government may have to find answers to such a question and more while stepping into the issues of governance. Tradeoffs are decision problems that everyone has to face—from an individual to a group. It is ideally about “this” or “that,” not “if not”² as on a flow chart. In practice it could be much more than a two sum choice, like none of these or more than that. The basic decision problem is in the model of “what is ‘this’ that if bartered can get ‘that’?” The style and methods of governance will not only vary from nation to nation, but also from government to government within the same nation even though there are standard formats for governing. The tradeoff a government receives for an action may not be similar to that what another government receives for the same action. This is important for governments to know (of course, they know it; it is visible in the responses by various governments to the Covid-19 pandemic in the new century). Every government managed them differently, specific to its own style, and requirement of governance.

Box 27.1: Myth, Legend and History—Time Travel to Now

Myth, legend and history (MLH) may be a better route through the tunnel of distorted reality for appreciating the associated facts with respect to an inquiry. The light at the beginning of the tunnel will lead to the quest. It is the end (from where it all began) in the reverse. This is how investigations are done in all “Who done it?” or “What happened?” cases in irreversible time. It is better to wade through the MLH sequence, not the HLM (history, legend, myth) to fade out distortions. HLM pathway is for academic interest whereas MLH is recommended for actual investigation. The MLH path unwinds the sequence better by reversing the distortions entangled in deep time.

Before probing, one may attempt to understand the meaning of tradeoff in this study. Tradeoff is a critical decision factor for any governing system, whichever it is from families to nations. It has to be taken seriously, because, people feel the changeover and can become restless. The tradeoffs should be executed carefully and smoothly.

Tradeoff is between two features, where both are not only desirable, but also equally urgent. One is sacrificed for another decisively. It is a situational decision in which a desirous something is discarded or given away deliberately for an assured gain of something else equally desirable. There is loss as well as gain in a tradeoff. Something decreases as something increases for that reason. It is similar to placing a jar of sugarless sweets for grandma in that suitcase already breaking at the seams

²The two posers are decision problems in a decision-making situation and, thereby, very different. Weighing parameters under such decision problems has to be done seriously based on compatibility with the two tradeoff choices. The famous Shakespearian quote “to do or not to do” is different from the pathetic house maker’s agony, “God, what to do now?” while managing a home.

while planning a long-distance visit home. Grandma just called. The decision percolates to the removal of something from the suitcase to make place for the jar of sweets. Goodwill of grandma is important though the removed item may be a personal favourite. The decision is mostly situational; that is important to know. Tradeoff is not in things alone. It could be in material, health, quality, reputation, power, job, desire, money, love, electoral votes, geostrategy. . . Tradeoffs can also be on the “same something” based on alteration.

Tradeoff dealings or decisions are under the full consciousness and conscience of the involved party. Humans encounter tradeoff experience innumerable times in life (Box 27.2). Assessing their values can be a difficult task. But it is possible in every field. The subjects involved may experience the gains differently.

Box 27.2: The Yellow Pencil and the Pretty Girl

The author once traded off his favourite yellow pencil with a pink eraser at the end, for sugar candy on a stick with a pretty girl in the school while in second grade (1952). The yellow pencil was quite a hit in those days among children. The sugar candy, on the other hand, was tastier than the chewable pink eraser for the author. But it soon vanished. The pencil with eraser, which once belonged to him, traded off to the pretty girl was intact in her hand. It was a bad tradeoff; he felt when the candy vanished in seconds. But soon he realised that it was not the sugar candy for which he traded the pencil. He felt it when the little pretty girl waved at him every time their eyes met in the school. He would blush; his heart would pump up. The tradeoff led to something very different from the products exchanged—the feeling of sweet and savoury romance inherent to humans. He behaved similar to Charlie Brown encountering the little red-haired girl, immortalised by Charles M Shultz (1922–2000) without even drawing her in his cartoon series, aptly titled *Peanuts*.³ Charlie Brown was willing to tradeoff anything in the world if that “little girl with red hair” would come over and sit with him.⁴

More than the sugar candy that melted away in the mouth; the friendship with the little brunette was lasting beyond the pencil for the author. Otherwise how could it become a subconscious narrative in a box in this book? That also shows that the value of a tradeoff can change with time. What was a gain once could also turn out to be a loss later. This variable makes any quantification of a tradeoff time functional. Simply put the value of a tradeoff at a particular moment can change at a different time. That is why tradeoffs are key factors that need attention while decision making in life, business and governance. Anybody or a human system engaged in a tradeoff

³Intelligent because the cartoonist drew her in the minds of readers without drawing the character on paper

⁴King, D. (2015). “Charlie Brown Never Found His Little Red-Haired Girl, but We Did” <https://www.vanityfair.com/hollywood/2015/11/peanuts-real-little-red-haired-girl>. Accessed 2 July 2020.

situation should mostly gain by losing that “something” in exchange as ownership barter at that moment. But can this argument apply in national security governance (Box 27.3)?

Box 27.3: Bad Tradeoffs Unlike a Candy

Tradeoff bargained with a pencil for a candy may trigger puppy love that may last forever as a memory incendiary in the long run as in the previous case. The romance still lingers. But where can a tradeoff go wrong disastrously? Every tradeoff is supposed to contribute a win-win gain for the parties at the time of executing it. But in course of time it could lead to disastrous lose to one or both of them. This is especially so in national security. There are plenty of examples in history where associated authorities taking either vile or irrationally ignorant decisions on tradeoffs in every aspect of national security elements. Examining them is left to the prudent readers, who have the time and access to information. The message in the box is that a tradeoff is a function of time.

Tradeoff decisions are viewed differently in different fields. In economics it is a decision factor as opportunity cost. It happens when the preferred economic alternative is given up for something else which is felt situationally better. It is a complex matter. The complexity, according to this study, in author’s viewpoint, is not the loss of money in the opportunity cost but by a different argument shrouded in uncertainty. If that is so, opportunity cost is only an imaginary knuckle for a turn. It is described further in this chapter. In the meantime, it is all about tradeoffs for the better as perceived by the initiator. Initiator is the one for whom one should argue the case. It is a relative expression. The opposite also is the initiator performing from the other side in an ideal barter of two entities. In the opportunity cost mostly there is only a single exchanger, the individual in the barter. It is the opportunity that is bartered by the initiator one for one. There will be certain differences when it comes to national governance. It is examined later.

Tradeoffs are natural companions in strategic decisions in almost all fields which the decision makers have understood as real in any situation. The other fields where tradeoffs occur regularly are biology, environment, climatology, population, engineering, technology, management, strategy, games, ethics, medicine, health, war, government, politics and so on. The tradeoffs in these fields and more are left to the individual reader to explore and examine. This study is interested in tradeoffs related to national governance aimed at national security. Tradeoff decisions are expected to lead to the optimisation of elements in various terrains and their integration in present-day national governance. Each element of national security is a tradeoff detonator to the other. That is why it has been originally said that the elements were mutually inclusive. Maximisation attempt in one can automatically create a minimisation impact on another though not always as a condition. The role of governments is to optimise governance to the desired yield in the process of NS_{max} . It will demand multiple tradeoff decisions.

Tradeoff decisions in governance invite interactions between various entities. Ideally decisions on tradeoffs in national security matters should be singularly focused—the well-being of people. Well-being of the people is the end objective of national security governance in this study. But the tradeoff decisions will be based on many factors that may seriously deviate from the idealistic percept. But attempts can be made to be attentive to the end object.

It is important to include advantages of tradeoff assessments in strategic national security and decision making in competitive tradeoff choices in national security strategy to pull off the best results in governance.

27.2 Governance and Tradeoffs

Tradeoff in government is what the government decides to gain by forfeiting a constructive activity that is highly valuable for another that at the moment of forfeiture of the first was more desirable. Tradeoffs are generated by such actions which are also equally thought out in professional governance. Tradeoffs underplay the results of the discarded activity and overplay that has been subsequently achieved by the alteration of course. Tradeoffs are based on straight line human thinking. Humans are not capable of multiline thinking at the moment and perhaps for a very long time into the future. That is a limitation. Tradeoffs, as they are, form part of the basics of governance most of the times. The decisions of governments also decide the stability of the prevailing political system. Each choice of government means another choice forgone. The tradeoff creates an opportunity cost economically speaking. The opportunity cost is helpful in quantifying the result of the tradeoff. Though widely used in economic assessments in calculating tradeoffs the author doesn't fancy the concept very much except for a stand-in metrics in case one needs to assess the loss against the gain academically. Opportunity cost is unreal according to the author. But tradeoffs are better to examine the difference that will be accrued by shifting decisions.

Governance invites tradeoffs in every step especially when the objective is national security which is the highest form of goal identified. It is also complex because the exact goal cannot be defined and known; hence the idea of maximisation of well-being. Tradeoffs in international engagements are quite common. In a tradeoff, a government is compelled to choose among one of the alternatives. It cannot choose both as one blocks the other. Hence the government will have to make strategic tradeoffs as a winning way to compete with itself for raising optimisation of well-being. Choice in governance involves multiple tradeoffs. Multiple tradeoffs in governance mean tactical manoeuvres at every step carefully evaluated for results. Crafting national security strategy demands such tactical manoeuvres. That highlights the importance of consideration of tradeoffs in governance at all times.

Tradeoffs in governance arise for various reasons. These are different from business decisions. National governance is not business or organisational management as they are understood and practiced. But the common aspect of tradeoffs in

national governance is that organisational management and corporate governance are pervasive in it especially when the environment is competitive. Competition is present all the time, though the style and demand may be different. Competition in national governance demands exceptional strategic acuity. There are certain differences of opinion in choosing a tradeoff in governance. The choice lingers on the questions of choosing what not to do or what to do. For some, a tradeoff decision is what to do whereas for others it may be what not to do. Many governments got stuck in choosing actions in Covid decisions in the typical Shakespearian stipulation of “to do or not to do.” The author’s approach is to follow the hunch coupled with deliberate surveys and assessment as time permits. Pre-assessment of tradeoff is a highly intuitive decision as one is almost known and the other is expected and therefore a blind bargain. A bird in the hand need not be better than the one in the bush all the time. The supporting factor in case of a wrong decision is that there are always alternatives based on feed backs to reverse decisions positively as the strategic interventions advance. But the government should be smart enough to notice them.

Governance has to focus on many areas to maintain the best results of decisions and optimise the factors based on the nature of the prevailing political system. But there are many common areas that any government will have to see. The critical factors are:

1. Well-being.
2. Checks and balances.
3. Rule of law.
4. Human rights.
5. Patriotism and treason.
6. Equality and efficiency.
7. Individual privacy.
8. Safety and security.

They are briefly examined below.

27.2.1 *Well-Being*

Well-being is the end objective, the goal, of national security governance. But it is like the horizon at sea with a difference. Sail towards; it will retreat. Move back; it will come forward. This is the beginning of the tradeoff. The distance the horizon will move will be equal to the steps one has taken directly towards or away from it. But well-being as a horizon behaves differently. First, well-being is not spatial like the horizon; it is a feeling that will differ from individual to individual. Second, it is caught between apparent security (physical) needs and perceived security

(psychological) needs, a weird somatopsychic⁵ mix that interacts with each other. Third, a government does not have much control over perceived needs of humans. So, well-being will still remain a horizon with a difference, a horizon that doesn't move like a physical horizon, but remains near as if one can touch, but unattainable. Well-being is a target that can never be claimed totally because humans will still thirst for more. Funny, isn't it? This is the dilemma of national security governance. This is also the reason for tradeoffs in governance focused on well-being. It is a catch.

Apparent security is an active governance protocol whereas perceived security is a passive adaptation in governance. Well-being fills within the two. The government's action is limited under constraints, which in better terms are explained as law of limitations. Human well-being in general lexicon and usage is taken as a broad concept, but in this study it is a never attainable but firm and perceivable target. It is the wholesome well-being, not material affluence or high-quality life alone. It is not the feeling of security but the experience of the "absence of insecurity." But the problem with the absence of insecurity is that humans will tend to become overly confident giving rise to apparent and perceived security needs. Whether these vacillations in human lifestyle are acceptable or not is a dilemma that will steer tradeoff decisions in governance aimed at human well-being.

It requires to be reiterated that well-being in the context of national security as defined in this study seriously deviates from the conceptual outlook it has acquired among people. It is not defined as it still remains unattainable by maximisation or a standard human perception. Though a relative expression, well-being is what the politicians assure to their voters if they come to power. Therefore it is taken as the objective of governance which perhaps is expected to be a goal when the shape is defined. Till then well-being is the future that any human will look forward.

It is also not possible to unify well-being as opinions will vary. The metrics will not match with the groups. Therefore it is necessary to find certain standards that may grade human well-being in a country. This will call for extensive studies on acceptance by people who are competent to accept the standards of measurement. It may help to measure the apparent security standards based on satisfied physical needs. But still perceived security remains.

Human well-being studies pass through multiple fields, multiple ethnicities, needs satisfaction, and many more. But one of the fields this study recommends is the tradeoff scenarios. This study has not been in practice and that itself needs further research. At the moment it can only be said as a probable route. Identifying the tradeoff, determining the best and then to see such tradeoffs have been followed in governance are some of the steps that could be taken in research to decide on the well-being factor of a social system. Economically an indicator is income in the system and external to it that influences it. Velocity of flow of money is another factor that could be arraigned from the consumption factor and pattern. It gives

⁵See Paleri, P. (2018). *Human investment management: raise the level by capitalising human*. Springer Nature Singapore Pte Ltd. p. 191.

economic security as a measurable indicator. Health is another important factor demanding optimisation of health security. These two factors among elements and enforcement of rule of law-based governance could be supportive of well-being for a country. But for the economic security and health security to become sustainable, other elements should also need to be managed optimally. Once the effect of well-being tradeoffs are arrived at, the indexing process of national security can be initiated. Whatever may be the study in well-being it will only lead to that of the human system of the country by itself, not individual citizens of the country. The personality factor as a wellness determinant cannot be applied in national security studies. It is also not important as well-being is a moving horizon factor. The well-being factor for this study therefore has to be taken as that of a group involving the following multidimensional factors:

1. Income and associated inputs.
2. Velocity of flow of money (through a person's hand by any means).
3. Health and safety.
4. Rule of law.
5. Personality (non-measurable for the purpose) (behavioural aspects with respect to self, career, family, society and community as a whole. These are mainly in the realm of perceived security.)

The tradeoffs in well-being should be to maximise the factors 1 to 4 by balancing other elements of national security. Governance should see that there is no negative tradeoff in the perceived security aspects. It can be constitutionalised and incorporated in rule of law (27.2.3). Even then objective measurement of well-being is presently not possible. Therefore, governments may exercise caution while deciding on tradeoffs.

27.2.2 Checks and Balances

The first step in establishing checks and balances in governance is to assign right duties with authority and accountability to people who will experience the right responsibilities by such allocation and establish organisational systems that will be interwoven to act as the controlling centres for monitoring. In this process there is certain degree of power sharing which should not intervene and contravene each other's duties and functions. Power is the fire that needs to be kept under control. Checks and balances will turn topsy turvy under unexpected situations in governance that may lead to predicaments including anarchy at the extreme if gone out of balance. The checks and balances can be affected under normal conditions of decision deficit as well as critical conditions under deliberate interference and other threats. The main issue is containing abuse of authority, especially those that are extraneous such as political pressures on bureaucrats and other employees.

There are no examples to quote the most acceptable system of establishing perfection in maintaining checks and balances in a governing system. It is not

surprising as the process is controlled by the law of invariance and limitation in the system. Therefore, it is a matter of achieving what can be within the constraints that cannot be easily surpassed. The executive, if constrained, may not be forthcoming to implement creative and forward-looking ideas and if not constrained may end up in power abuse leading to corruption and malpractices. The policies of a government for checks and balances, therefore, are subject to tradeoff decisions. Liberal policies to provide freedom and transparency may invite abuse of power leading to corruption. Does it? Well, that is a catch even in tradeoff arguments. In the effort to strengthen checks and balances a government may have to sacrifice transparency, and stress upon power hammering through stringent laws, punishments, monitoring, surveillance and enforcements. This model brings rule of law as a governmental activity which is not an element of national security. This has been mentioned in the early chapters. Rule of law is a task of governance. It also shows tradeoffs are often present in the activity profile of governance. The national security strategy therefore should cater for the ambient conditions of law enforcement to establish the rule of law in the national security strategy. This is where the concept of enforcement friendly laws matter (Chap. 8).

A government will have to decide on checks and balances based on the degree of control it is capable of exercising through enforcement friendly laws (how friendly is friendly?) and how much the people want. Arriving at what people want can be a cumbersome process as people's desires are neither uniform nor outlooks standardised. Some governments, especially politicians in government, may take advantage of this dilemma. The answer has to be arrived at by interpolation as well as extrapolation of factors besides various surveys and trial and error methods in deciding the degree of laws and their enforcement friendliness for bringing out reforms. Every nation experiences it. For example, the government of India may have to make quite a few tradeoff decisions if it desires to introduce a uniform civil code that will establish checks and balances in the diverse social system (perhaps the most intense in the world) in equality and secular outlooks. It is not easy as the social system itself can get into groups affecting the unity of the multitude of human systems in a diverse nation. But still it can be done and is necessary for any nation under national security governance. That is where the tradeoff decisions play their part.

Checks and balance between the judiciary and the executive is another area. One is considered conservative and the other liberal at the outset. But in reality it need not be so. It is a matter of political system. There are countries where the judges have been assassinated as much as the politicians. The fear of assassination and mess up is what makes those in positions of power being covered with personal securities. It is applicable in every country. Security provided by the law enforcers to bigwigs keeps the lower public exposed to threats without protection. Increasing security forces denies money for development works or other things necessary. It is a burden for many countries. Promoting and loosening checks and balance in governance provides a model for tradeoff in governance. It is as much an activity with the executive as it is with the politicians. It is judged by the judiciary only when cases of abuse of power reach them along a route that the executive decides. The *suo motu* (*sua*

sponte) decisions by the judiciary on checks and balance are rare. *Suo motu* is an act of authority which by itself can be treated as a violation of power and considered as judicial activism.

One of the detrimental issues in governance is rent-seeking. It is a situation when an individual or a group as an entity seeks or attempts to increase their own wealth without creating or generating benefits for the system or society. This is done by violating the existing checks and balances arrogantly and impiously under power. In this process the rent seeker manipulates and exploits the economic resources which otherwise belongs to the system. Economic resources are allocated inefficiently and for the benefit of the allocators. This leads to various financial and economic situations in the society such as income disparity, inequality and depletion. Overall economic efficiency of the system collapses. The benefit is only to the rent seekers. It is a kind of economic leeching to the undeserving. The check and balances collapse under such situations of power abuse. The consequences are not only for the public but the system as a whole in terms of loss of revenues to the treasury and competitive disadvantages with long-term results. Rent-seeking encourages subsidies when production falls under situations of recessive economic slowdowns. When government provides subsidies to improve production the producers may start companies to obtain the subsidies rather than increase production. This is also the case in situations of banks accumulating non-performing assets in the absence of checks and balances in recovery of loans.

Rent-seeking is one of the favourable approaches of politicians in generating wealth. It was defined by the economist Adam Smith (1723–1790) who paved way for the idea of capitalism and free-market economy. Paradoxically he also opened up the economic term rent meaning payments in excess of resource cost. The benefit is not to the society but to the rent seekers. There is no reciprocal contribution of productivity. It is easy for them with tremendous power to manipulate and favourable to industrialists to make profits without innovation or creative engagements in production. Simply put the rent seekers bribe the politicians. But there is a tradeoff paradox in this method of accumulating wealth for own purpose. This inconsistency called Tullock Paradox⁶ brings out the possibility of the voters rejecting such politicians and defaming the companies engaged in crony capitalism and other aberrations of rent-seeking. The second paradox is the competition among politicians for rent-seeking that will push down the overall cost of the detrimental act. There are many rent-seeking activities that perhaps is the main source of political income for individual politicians. Rent-seeking survives on government-funded social-services and social service programmes. The familiar ones are

- Granting subsidies.
- Lobbying for benefits.

⁶“Rent seeking.” <https://corporatefinanceinstitute.com/resources/knowledge/economics/rent-seeking/>. Accessed 04 August 2020. Gordon Tullock (1922–2014) was an economist who linked economic with political issues known for his public choice theory which carries the rent extraction theory.

- Executing grants.
- Tariff protection for better income.
- Taxi licencing by capping the limit for increasing the income of incumbents. A licence to operate a taxi in New York City can go over a million dollars.⁷
- Price control threats that may increase the cost to the concerned industries.

All these are politically possible as rent-seeking actions by politicians for a price. Politicians' acuity as rent extractors is in identifying more and more rent-seeking opportunities. Rent-seeking theory becomes rent extraction theory when the rent-seeking shifts its domain to a coercive environment where political system threatens rent for special favours.

27.2.3 *Rule of Law*

The tradeoff in rule of law, which is an activity of national governance, is in making the law and enforcing it. The lawmakers could make a law stringent or too liberal depending on the pressure of governance and also their rent-seeking attitude. The law enforcers may look for tradeoffs by violating the law. When the enforcer violates law, the principles of rule of law go against the very purpose of enforcement as expected by the public. The public wants the law enforcer to establish rule of law. They are also aware that the enforcer may violate law, which they have to enforce, for a consideration. The enforcer therefore gets into a tradeoff situation which is also applicable to rule of law.

For the enforcing agency this scenario, where the enforcer violates law, is a dilemma of different dimension. The agency expects high level of integrity among its people, the enforcers. Integrity of enforcers is also important for the criminal justice system. The system cannot function effectively unless there is integrity among law enforcers. The law is, therefore, more applicable to the enforcers than others—the violators and the public. The violators expect the enforcer to be lenient or slack on enforcement, whereas the public expects the enforcer to provide safety and security. There is clash of mindset. The relationship between the enforcer and the public is song in any governed system. It is this strength that also makes the public lose confidence in the enforcer if they themselves violate or work in contrast to the rules. The enforcement, justice and community systems therefore are intertwined in a complex fashion. Within the paradigm of tradeoff the three systems behave differently and sometimes strangely which could be seen in various social projections—media, book, movies, etc. Upholding responsibility is what the public wants from not only enforcers but also other government agencies. Integrity among enforcers means the normative inclination to resist abusive temptations associated

⁷<https://www.libertarianism.org/blog/introduction-rent-seeking>. Accessed 04 August 2020. An introduction to rent seeking.

with the authority delegated in job assignment. Corruption or lack of integrity undermines trust and confidence, and being viewed as untrustworthy.

27.2.4 Human Rights

Humans often reach the brink in their survival process where they may tradeoff their rights. It is a socio-legal issue related to the rights of an individual to leave a peaceful existence without causing impediments to another person's rights. It is a kind of live and let live principle where an individual is entitled to human rights without discrimination. The rights are interrelated, interdependent and indivisible. International human rights law adapts the universality and inalienability of human rights. There are even arguments that the international human rights issues may be suspended to meet rapid developmental programmes.

In an economically fast developing world respecting human rights, as demanded by law and society, becomes difficult unless declining tradeoff is acceptable. Attention to human rights depends on the demand for development. Policy makers and academics believe pragmatic development may involve tradeoffs in human rights. Development and commitment to human rights are believed to be competing concerns. Within this belief the problem can be turned around as the need for development to establish human rights. In such case development becomes a condition for human rights. The tradeoff is not sacrificing human rights for development but altering development towards human rights. It will require suitably altering course of development. It's a job of governance. The situation can face impediments in the political outlook clashing with other tradeoffs. The issue has to be seen whether development is complementary or competing with human rights. Often it is left to the tradeoffs accepted by the decision makers in governance. Governance therefore could be steered for rapid economic growth and development without surrendering socio-economic equity of people. Human rights whether individual, social, economical or political are expected to be compatible with development and governments need to recognise them in governance procedures.

27.2.5 Patriotism and Treason

The author was prompted to consider patriotism and treason, two ambiguous and immeasurable personality traits of individuals and groups, in the study of national security, while appreciating a quotation from Alexandre Dumas (1802–1870), the French author. His quote was, “*The difference between treason and patriotism is*

only a matter of dates.”⁸ The quote was fine for the period. But those who are not patriotic cannot be tried for treason. There are other factors also in the line of patriotism and treason, such as nationalism and all kinds of isms and their likes that define a person’s attitude towards the country or the system. Anything against can be handled by law depending on the seriousness of the act not just the thought. Patriotism is a thought and so are other feelings towards one’s country. Patriotic act or an act of treason is dealt with separately by the country. There is no serious tradeoff in accumulating treason in thoughts leading to any act of treachery against one’s country.

There are many such quotes from thinkers on the subject. It pours all the time. An indirect statement can be seen in *three Musketeers* of Dumas published 1884. The slogan “one for all and all for one” (*Un pour tous, tous pour un*) attributed to D’Artagnan, the central character, just proclaims the need for patriotism when sovereignty of state is at stake. Patriotism is expected to create a feeling of responsibility. It is given weightage by the governing and responsible side by suppressing the tendency of treason to tradeoff for benefits among citizens. Interestingly the phrase in Latin is the unofficial motto of Switzerland, a nation of limited people⁹ that maintains high standard of well-being in spite of the concerns of getting overpopulated. Their tradeoffs in national security are well contained in countries that aspire for higher well-being.

Patriotism is connected with nationalism or rather the love for one’s sovereignty in one’s country. Any rejection of patriotism amounts to treason. A change in patriotism causes an equal entry of treason in theoretical terms. Patriotism starts with the national flag and anthem a person adopts close to the chest as seen in behavioural projections. Patriotism means feeling for one’s country and the people. The feel for the government is not patriotism. Make it govern is patriotism.

Treason is not indifference to one’s country. Majority of people in a country may be indifferent or oblivious to it. It is for the government to make the population cohesively patriotic. It is a part of governance that is not at all easy. A traitor is the one who violates the laws associated with the national security of a country. It can be active or passive. Treason is associated with law. The traitor benefits from the tradeoff.

27.2.6 Equality and Efficiency

Equality is sense of fairness in treating a person equal to others or self in every aspect of governance. This could also be done by giving a hand to the less equals to raise them to the level. This comes primarily in resource allocation. His needs and wants

⁸<https://www.goodreads.com/quotes/193303-the-difference-between-treason-and-patriotism-is-only-a-matter>. Accessed 12 January 2020.

⁹Population 85.7 lakhs (2019).

are shared equally. Efficiency is in making equality possible by making the best out of the relatively scarce resources. There can be tradeoffs in equity balancing with efficiency. It is also the central principle in economics. In governance, equity moves beyond economics to overall well-being. The principles however remain same though the process is highly dynamic.

These, seemingly simple seesawing factors, in theoretical explanations, can cause complex problems in national governance through tradeoffs. Policies that a government may take can create exploding situations among people under various situations—ethic, political, environmental and so on. There is no place in the world where people consider equal. The third element that stands between efficiency and equity is the demand of the people to be treated better than the other predominantly in subgroups. That is the very basic of group formations in unequal situations.

Exploitation of natural resources is an economic issue. But it can be a question of who get the maximum benefit out of it. The entire national politics may turn around on such inequalities. A development project may be objected by people on environmental tradeoffs. Ideally the objective of the government will be in the larger interests of the nation. Local interests may not find place in overall national development. Local interests can hold precedence over national interests. Tradeoffs between efficient use of resources in that area and equitable distribution of resources to the people there cannot be ruled out. Balancing inequality in such cases can be done in many ways depending upon the political will in governance. One of them is making good of what the victims lost by making them the stakeholders in the developmental works.

Tradeoffs between equity and efficiency in governance can be many. Government may have to take hard takeoffs at times. But there are also times when equity and efficiency go hand in hand. A good health scheme can create healthy people who in turn will pay back through productive employment. The first turn for a government in case of an epidemic pandemic situation is preventing production loss. Tax concessions, health care programmes, land reforms, welfare programmes, educational policies, etc. are the methods available to the government to balance the tradeoffs through measures appropriate to the situation. The factors to balance equity and efficiency will involve socio-economic-political measures. Views of the government can keep changing on tradeoff between equity and efficiency. An example is taxation that keeps generally changing annually when financial year changes. All the decisions in the socio-economic-political framework change every time a new government takes over. It also means there can be different kinds of tradeoffs between equity and efficiency. In any form of governance there will be two kinds of cases: one, where efficiency is compromised for equity and the other where equity is compromised for efficiency. The tradeoffs are acceptable if maximising the well-being is the sole objective of governance.

27.2.7 *Individual Privacy*

Economy of a nation turns around business, which in turn depends on data that when refined provides the needed information for decision making. Everything that leads to good life needs information at all times. Human lives today are heavily impacted on data and how they are utilised. Data acquisition often gets into a serious compromising situation while acceding to data that are private. Public and private organisations and agencies are in a hurry to capitalise on data acquisition and collation to expand digital inclusion and the data economy. The rush in data hunting has also given rise to illegal data accumulation through information traffickers. Use of data to solve problems and issues like contact tracing or ban of security violating apps have brought the privacy debate centre stage.

There is growing consciousness among people about their privacy. This has given rise to ethical data usage practice as organisational responsibility to protect privacy of people. Governments have to ensure citizen privacy is not compromised. It requires serious governance in ensuring privacy through restrictions in data collection, prevention of data piracy, containing information trafficking, creating public policy in data acquisition and privacy, and other aspects while simultaneously balancing developmental national needs. There is renewed push towards privacy of data. Data protection regulations are required to be enforced to maintain public privacy. Establishing personal data privacy is also required to establish citizens' rights. But such restrictions can also stifle innovation and knowledge endeavours. The tradeoffs in information and privacy are in the region of development by advancement. This can affect overall national investment in venture capitals. Consumer trust in companies that are concerned about data privacy and data protection increases in a society that is aware. Personal data protection, therefore, has become a government activity. This end also reflects in the element of cyber security through cyber laws and cyber ethics. Information gathering in the area of security had come under heavy public criticism after the Snowden episode. Edward Snowden brought out the PRISM¹⁰ programme of the American National Security Agency (NSA) into public domain through various disclosures. Snowden, the American whistleblower, copied and revealed classified information on public surveillance by US Government when he was a Central Intelligence Agency (CIA) contractor as well as an employee. The disclosure to the media besides putting US government in serious embarrassment also strained its relations with many countries. It was followed by serious debates and discussions the world over on security and piracy.

The value of privacy is extreme for a human being. Ironically there is a tradeoff between information technology and individual privacy. There cannot be a better example than the uneasy days of forced human isolation and impeached government-controlled privacy at the outbreak of the virus of the century—Covid-19 the fancy name for a particular variety coronavirus appeared from China. Covid

¹⁰Codename for a programme in which internet communications are collected from various internet companies in the United States.

took away the year that would have been best remembered as the beginning year of the new decade. It extended further. The tradeoff in the Covid data gathering is between rights to privacy lashing with right to life. It is more an ethical imbroglio for humans than intentional data trafficking. Acquisition and collation of personal data of an individual if done in the right earnest interest of saving that person's life shows an ethical pattern. But I can also lead to the assumption that the authorities are encroaching individual privacy for the sake of illegal data acquisition, or using the situation to gather the personal data of the hapless victim in the unethical mode. Right to live and right to privacy becomes conflicting rights under such situation. The Covid issues also show the governments are working on trial and error methods without useful precedence to make decision. The tradeoffs therefore are hard to debate. The judiciary may also look at the rights in accordance with the law and differently from the governments as it feels right. Within the right of an individual to life the government can ensure chain of custody of personal data with due concern for both under strict restrictions to safeguard both in contravention to tradeoffs of one over the other. It is a decision the governments can make.

27.2.8 *Safety and Security*

Tradeoff in security is the cost of the overall physical security of the nation and its people. It is big money that provides enlarged opportunities for tradeoffs. Here, one of the strategies of the other country, the friendly neighbourhood opponent or the long distance competitor which everybody is, will be to increase the cost of security of the other. It is not necessary that the other will adopt it. Besides, this can be identified. A strategy that is known can be countered. The idea is to bleed a country economically or by much cruel methods, with a view to keep it suppressed, is a known and strategy even if the adversary doesn't adopt it. It fails ab initio if the other has money to counter it. But it is not so when the country cannot withstand the money might of the other.

Here one comes into a major issue. What is the cost of national security? There are two options here while budgeting: either budget for physical security known as internal security, homeland security and so on. . . or budget for the overall national security. But the overall national security is the nation's budget of governance. The tradeoff between national security and physical security will depend upon this decision.

27.3 Factors that Affect Tradeoffs in National Security

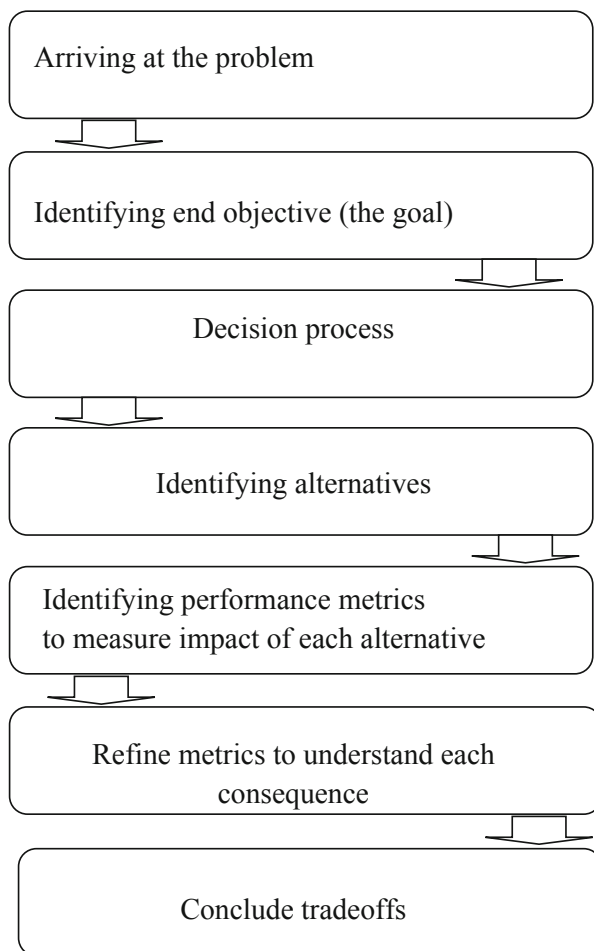

Many factors affect the tradeoff environment within a particular country. On one hand, it may include availability of resources, absence of or inability to exploit technological innovations, state of economy, process deficit for manufacturing,

conflict and geostrategic pressures and so forth. On the other, there could be opposition to governance from the anteforce that crosses the requirement of checks and balances in governance. In between there is a stage where the government is not able to make the right decisions to understand the tradeoffs. Decision-making stagnations can seriously impact tradeoffs assessments. An opposition in governance is expected to maintain checks and balance. But objections for the sake of objecting can make the opposition an anteforce to governance. Governments will have to have the professional expertise in decision making and converting the power of anteforce in favour of governance which will improve tradeoff benefits. This may be a wish list. But it is necessary for taking advantage of tradeoffs. Often decision tradeoffs benefit individuals or organisations, not people in the overall. That may happen not by abuse of power but also sheer incompetence in governance. They have to be handled separately by changing the art of governance appropriately. These cannot be categorised or listed out in “do it yourself” instruction kits for use by governments and their officials. They have to identify them appropriate to the country and situation. This is the reason for the statement that countries cannot fail but governments can. A government or its head is not the country. It is the agent of the country for the people and of course by the people whether electoral or otherwise. Failed governments are those for whom the tradeoff decisions were not appropriate to the situation and system. Some may be deliberate; some may be involuntary out of sheer inability to identify the right course to take by crafting the appropriate strategy for intervention.

Tradeoffs are generated while decision making. Therefore the tradeoffs decision model should be within a suitably designed framework. This will depend upon the objective of collective decisions and consequences of each decision. Normally decisions identify alternatives. The decision makers should examine the consequences of each alternative and determine which set of alternatives provides the best solution. In this process the consequences of alternatives and associated tradeoffs are to be identified. This has to be carried out analytically in national security-related decision making, which means in everything about governance. The best alternative is ideally or believed to be the one that is appropriate to meeting the set objectives towards the goal. The consequences of these decision alternatives need to be understood to examine the tradeoffs. There are many methods to identify the suitable alternative among many identified through decision making. They have to be analytical, deliberative and intervention friendly. More suitable methods in relation to the problem too can be devised by the government.

In any effort, consequences are the impacts of alternatives as measured by identified or selected metrics. The performance metric goes along with the alternative that is implemented for performance measurement. Otherwise it is cancelled from the overall implementation of decision in governance. The final step in a decision process is identifying tradeoffs for consideration of the alternatives. The tradeoffs that are best for the objective are selected and alternatives from the decisions process are chosen in governance. The factors in such a situation can be many that are impacting the decision process. The outline steps in this process of identifying the factors are given in Fig. 27.1.

Fig. 27.1 Outline steps—
identifying factors of
tradeoffs

The factors that affect tradeoffs will be generated at any of the above processes. The conclusion about the tradeoffs that come at the end will be affected in an order that is proportionate to the steps ahead of it. In other words if the goal is not defined correctly at the starting point the entire assessment of the tradeoff at the end will become wrong. There is dilution at each step in the process from the assessment of goal to identification of tradeoffs.

27.4 Balancing Tradeoffs

Tradeoff situations create challenge to decision makers. It is a conflict situation. The decision maker is the government in national security governance. The factors that are involved in decision making under conflict are to be balanced according to the norms of governance in favour of the people. The society and the government are mutually dependent to the extent that the people are the government even if it is not an elected system. It is so even in critically autocratic system and holds good as long as the country has a government of some sort. The people know and approve every governmental system either under freewill or fear, the two extremes which relatively speaking are alike. The moment a citizen doesn't object a government he or she is a participant. The person may oppose; it is not objection because there are still groups of people who approve the government. That is the same scenario from autocracy to elected democracy. Mathematically the models are similar in national security studies. It is under this theory that a citizen is considered not just a stakeholder but a participant in governance. Opposition and approval are the complementary sides of checks and balances. "Overthrowing" a government in a coup or an election has the same considerations in tradeoff metrics. People participation thus can be measured relative to a nation. The scenario changes when the government is absent though the country exists as a geopolitical entity or slipped into total anarchy. Every government has peoples' participation by approval, either by total consent or fear. In an electoral democratic system, the people approve the government under consent; in the extreme case of autocracy, they participate in governance under fear. The social contract (Box 27.4), the relationship between the state and its people, holds the key in balancing tradeoffs in governance. The individuals consent to forgo their rights and freedoms to a great extent even in full-fledged democratic models.

Social contract allows for maintaining certain degree of trust between the government and the people. It may vary within a country and also among countries with respect to time. But the trust exists. It is under this truth that people agree to be bound by the rules the government makes. They feel the government will not use them for a tradeoff. The problem is when there is a breach in the trust the people have in the government. It is for the governments to see the breach never happens. The tradeoff balances at the very moment it is established. The problem here is that this is not established by law anywhere in the world. As a result people will have to wait till the governments change.

Box 27.4: Why Social Contract is Important?

Social contract is a vast topic.¹¹ Vast because it's debatable and is not based on law but human intellectual evolution. It is the responsibility as well as accountability of a human entity (individual or a group whether formal or informal) has towards the society or human system as if there exists an implied contract. In the case of national security governance there is a human-nation relationship in which the nation accepts the contract by accepting the people within by citizenship. It is vicarious because a nation has no other choice. Whereas, humans have the opportunity to shift through many formal or informal processes. But the social contract with a nation still remains for citizens. It helps in mutual existence. While the nation does it just once, humans will have to reciprocate constantly. That is where the governments have to focus. This is also the crux of the four-point theory explained between nations and its people in Chap. 25.

27.5 Cost of National Security

First the cost of national security is not the cost of military or defence or armed force budgeting. Cost of national security under the concept of overall well-being is the cost of governance itself. Tradeoffs are one of the critical factors to look into when the cost of national security is assessed. It is important while preparing national budget but seldom budgets are prepared that way. Preparing budgets and assessing costs are the prerogative of governments as convenient to them. Ideally, it should be based on the cost of national security (CNS). Yes, it is an idealistic concept in the first look. Governments budget annually or otherwise under various heads, but it is not necessary the money will be spent exclusively towards national governance. It is also not necessary that national governance is towards national security. Even then it is not necessary that national security concept for the government is aimed at the well-being of the people as defined in this book. All these depend on the people in authority vacillating in their decision making processes true to the nature of humans and the system they belong to. Hence budgeting is idealistic *ab initio*. It leads to the next step of idealistic realism before it turns to realism and deteriorates to realistic idealism before finally burning off. At the end governments would have overspent or underspent. Underspent is called back and carried forward to the next season. The cycle repeats with due allowances given to the changes in policies in between. There are countries with budgets that will be far below the budget of a business corporation or the next door trafficker. But the question in budgeting is not just money but the overspent underspent conundrum. Overspent may yield extra inputs but underspent may cause short results. Besides, the author believes overspent (within checks and

¹¹ Paleri, P. (2020). Corporate social responsibility: concept, cases and trends. Cengage Learning India Private Limited. pp. 27, 60.

balances) is a better situation than underspent because it increases the velocity of money flow in the system. Besides the adage “what goes around will come around” is nearly true in money circulation. Velocity of flow keeps money possession live and active in the system. The much practiced and advised parsimonious practices are considered to be bad for the economy. They can make the money flow stagnant in the system. Stagnant economy breeds discontent, which is against well-being in the system. Here it is not the cost of economy and spending the budget that matters, but the overall return from the budget towards national security.

Within the budgeting process, the cost of national security varies or rather dings-dongs between the two limits. It starts as an idealistic forecast and ends in realistic idealism. In this scale of distancing, the reality amount will be somewhere in the span of the reality spectrum, somewhere around the median. This will be different for different countries. This amount could be used to measure and compare national security with other countries, though NSI is the real factor for comparison which need not be according to the budget or cost, but the outcome or results. The cost of national security in this study is not the national budget which the governments keep talking about or how much money a country spends in the preparation for war to protect itself as normally considered. It is also not anything that a government decides to spend in national governance. But, it is there within all these. The cost of national security can help the government to arrive at the effectiveness of governance but the efficiency is a ratio of the input with quantum well-being.

To understand the cost of national security one has to appreciate the elements that go into governance towards national security specific to a country as well as common to national security in general. The well-being is a standard scale that has to be arrived at for all the nations in a common measurable scale. This means there can be a country-specific scale as well as a global standard scale which could be arrived at by applying the national factors to the national security assessment. For example, for a country where well-being means national happiness, the effectiveness and efficiency of governance will be as per the national parameters, but for comparison with other countries it has to be assessed by application of the country factor. It is a complex process and, therefore, needs to be linked with NSI which can be standardised relatively. Even then, there can be admissible and non-admissible errors. The human system will be able to refine the process gradually in course of time once the national security concept for maximising well-being by governance is implemented. It also includes the people becoming capable of assessing their governance through the accepted metrics. Today nobody in a human system can measure the competence of governance that results in prejudiced and incorrect information through socio-political grapevines. It is time for a change, or rather quite late, as the author feels.

Accordingly, one of the ways to assess the cost of national security will be by examining the cost of governance in relation to the cost of optimising the elements, cost of integrating each terrain, and overheads associated with each element and the terrain applicable to a country. This ideally should be the sum total of 48 heads (16 elements +8 terrains +24 overheads combined to elements and terrains) in budgeting each of which in turn will be the sum total of various factors associated

with the activity which will be different for every country for assessing by uniform indexing—NSI. They are given below.

1. Cost of optimising each element of national security (16).
2. Cost of integrating each terrain (8).
3. Overheads (24).

The cost of national security for each nation may vary, as some countries may not have to spend for all the elements and terrains. Besides, there are other factors also. Demographic density is one of them. The only constant in national security is the individual human. Nationality does not change human aspirations and needs and wants. Well-being is what every human looking forward to irrespective of nationality. Human feelings are the same even with the tint of conditioned nationality. This will make an interesting study. There will be a host of questions? Is the growth of nations limited to its own maxima? Does that mean a particular nation cannot grow beyond a level and move ahead of another as mentioned earlier in human system? Will the cost of national security affect NSI? There are more.

But the interesting aspect is that the feeling of total well-being or the average per capita well-being will be in the same unit for comparison. This could be the NSI that quantifies the prevailing well-being among people averaged for the period of calculation which could be limited to the optimum short. There are nations that may not have to optimise all the 16 elements or the 8 terrains. Accordingly, their cost of national security may reduce. The well-being can increase or decrease as it is not proportional to cost but the style of governance. This aspect too will reflect in the calculation of effectiveness as well as efficiency of governance. This means that a country like India, which is demographically dense and socio-politically diverse, may have more responsibilities for the government than another, say, Finland. But when adjusted for national security, the well-being of the people, they will be more comparable with Finland than under present methods of comparative indexing. Presently the comparability of nations or a nation at different times is not identical. The terms, such as GDP or happiness index, may sound identical but not comparable as the system variations exist between and within. This is the drawback of the present system. The comparison of the countries as per the indexes of today such as GDP, happiness, hunger, environmental degradation or simply filth is not based on equitable principles.

The real variable at the end is the acuity, effectiveness and efficiency of governance. Ultimately for every nation it is the government that matter. And for a government it is their style of governance that matters.

Governments and the experts may have to decide ways accounting cost of national security as mentioned above or in any convenient way so that the outcome, the well-being, is identical for each geoentity though the input analysis may vary based on demand. Therefore all the three elements are variables. National security elements, terrain specificity and overheads are variables from one country to another. The costs need to be measured and recorded individually based on a period. The cost of inputs is calculated and outputs are measured for calculating the overall well-being against a global index so that the NSI is globally standardised. The results ultimately should

aid in measuring the performance of government in providing well-being to the people. The primary cost elements are examined briefly below.

1. Cost of optimising each element of national security.

Governing each element of national security incur cost. This becomes complicated based on decisions of the government and the tradeoffs experienced among elements because they are interactive in a mutually inclusive manner. This is the challenge for the government in balancing the cost. In all the decisions the objective is to optimise one element against the other and maximise national security within the law of limitations to governance. Law of invariance provides the key. Extreme care and professional acuity is required from the side of the government for optimising the elements at any particular time.

2. Cost of integrating each terrain

There are eight terrains identified as of now for integration. Every element could have its own part to play in relation to terrain specificity. This is also a variable cost to the nation and the role of the government to optimise it for integrating the terrain with national security.

3. Overheads

The overhead costs in national security are those that are not primarily related to national security strategy but collateral to it.

All the three primary cost elements will comprise fixed and variable costs. It is for the government to decide their values and applications besides the nature of financing them whether deficit or surplus based. While a surplus outlay may point out the financial prosperity of a country the deficit outlay need not be taken as a financial weakness. An affluent country too can resort to deficit budgeting. It depends entirely on the policy makers' choice of value engineering the cost of national security.

Ultimately it is the national security strategy of a country that should drive the cost of national security. It should never be the other way around. But in most cases the quantum of national security maxima depends on the cost that is affordable to the government. That too, after meeting other requirements of governance that is not related to it. To optimise national security governments need to make smart decisions, follow correct ethical practices, establish rule of law and accounting, ensure audit sensibility and firmness, and control waste by value engineering national security governance.

The outlay for budget should be decided taking into consideration the interactiveness of each element and integration factors of terrain specificity and minimising overheads. It is a task for the policy makers in government. Continuous reforms to national security spending are essential for cost-effective national spending.

27.5.1 *Welfare State and Free Dolling*

Welfare state is a terminology in vogue in socio-political sciences. It means a nation that follows a system wherein it undertakes to protect and ensure the welfare of its citizens by dolling out money either directly or indirectly (in kind and other means but not cash) in a selective manner. In this statement welfare is not well-being under the definition of national security. It is about needs as decided by the concerned government often mixed with wants including the wants of decision makers in government.

It is a kind of governance without governing or easy way for a government to survive short term. It is convenient governance. It exists all over the human system and leads to many negative collaterals including power abuse and injustice breaking away from equity and equality principle of national governance. It is a kind of Sherwood system¹² where the relatively rich are robbed on behalf of those who are not so rich. Taxpayers will argue the government is misusing “their” money to help people according to their own decision (see Sect. 27.5.2).

Any well-being acquired through welfare in a welfare state should not be accounted in NSI acquired by GBNS. The former is temporary and set precedence for decreased productivity. In official terminology the welfare systems include providing financial or social aids by means of grant, subsidies, pensions and individual or social benefits. But some of them such as health care, insurance, etc., cannot be part of a welfare system but more so well-being system through GBNS. Therefore, it is important to assess the welfare and corresponding well-being carefully in a welfare state which most of the nations are. In every nation there is a welfare state primarily that ease up governance, which otherwise is an extremely difficult human task. The need to adopt welfare measures as a convenient governance process shows the absence of efficaciousness in governance. This in turn indicates possible ethnic fragmentation in the system. Though it is not appropriate to ridicule welfare measures in a human system, a government will be able to achieve the desired welfare measures by incorporating them in GBNS by adopting more appropriate and professional measures. This way the overall well-being can be maximised instead of momentary welfare.

The foundations for the modern welfare state in the UK were laid in 1942 by the Beveridge Report, 1942.¹³ The establishment of a National Health Service and the National Insurance Scheme were implemented by the Labour administration in 1948 according to the report. But strictly they are part of governance and not the Sherwood system mentioned here. There are many countries that follow the latter which this study considers as what makes a state a welfare entity by freewheeling

¹²Followed by the legendary and considered to be fictional Robin Hood of the Sherwood Forest or any of the group and system that rule locally in a limited manner legally or illegally. The historicity of Robin Hood is not proven.

¹³The Beveridge Report is a UK government report prepared under the supervision of William Henry Beveridge (1879–1963), the liberal economist.

governance sans SNS. Governance is an internal matter of the people and the governments and therefore for them to decide.

The statements so far are to avoid semantic dissonance while using the term welfare state. It occurs frequently in political science and similar others. It is important to know the semantic expression contextually with clarity of perception. A welfare system is what a welfare state uses for governance. Or welfare state is the one that governs through welfare systems which seemingly are the easiest means of governance for a government especially to overcome a difficult situation temporarily. Such governance may lack competitive acuity. National security governance is a competitive activity. It needs strategic application of interventions. Welfare or free drolling measures do not aid competition and thereby growth and sustainability. According to one of the definitions in vogue, the government of a welfare state protects and promotes the economic and social well-being of the citizens, based upon the principles of equal opportunity, equitable distribution of wealth and public responsibility for citizens unable to avail themselves of the minimal provisions for a good life.¹⁴ According to Sociologist Thomas Humphrey Marshall (1893–1981), the modern welfare state is a distinctive combination of democracy, welfare and capitalism. This study considers the statement idealistic with a realistic touch in the present scenario that is not appropriate for competitive governance and, thereby, not appropriate to counter the sapien predicaments of living in the present and futuristic scenario. This theory idealistically cannot be applied to countries that do not follow democracy similar to others who practise this system. Besides Beveridge's idea of welfare state was ideally suitable for a World War scenario, that too the Second World War, meaning under extreme situation when GBNS was difficult to practise when the world was in turmoil and contusion where human well-being hit the rock bottom and turned to despair. The welfare state principle helped the world, especially UK, to tide over the situation during war and immediate post war period (Box 27.5).

Box 27.5: Is the Principle of Welfare State Passé?

Yes, for two reasons. One, the world needed something similar to the welfare state propounded by the Beveridge report in a situation of extreme trauma and confusion that existed at that time. Today such situation doesn't prevail in the world. The world has advanced beyond hunger and agonies of similar kind, though there can be different opinions. What the world needs today is competent governance with a well-aligned SNS and NSS. Two, the idea of welfare state of Beveridge Report is not exactly what the governments, politicians and organisations practise today in the name of it. The power abuse has been too strong under affluence and disaster scenarios equally. The affluent sector is involved more in extreme power abuse than the weaker sectors of authority. Even disaster management has been up to corrupt practices and abuses as an

(continued)

¹⁴“Welfare state.” https://en.wikipedia.org/wiki/Welfare_state. accessed 20 November 2020.

Box 27.5 (continued)

opportunity for the powerful in authority. This has been highlighted by author Sainath in his well-researched book in 2000 which is still valid two decades later.¹⁵ Today the idea of welfare state is an opportunity for power abuse. This is hypothetical, though.

The Beveridge's original idea of welfare state was actual governance advocacy rather than doling out money to people. Beveridge proposed social welfare reforms in the UK in the middle of World War II to overcome the want, disease, ignorance, squalor and idleness (the five giants) through post-war reconstruction. The Report became popular with the public and also ideates professional governance rather than free doling. It caught the name of Welfare State which ideally was about human well-being perceived as welfare in those days. It formed the basis for post-war reforms that included expansion of National Insurance and creation of National Health Service. Today the term welfare state is passé as national security governance can take care of human well-being in a much advanced manner providing apparent security aligned with perceived security to people through GBNS.

27.5.2 *Tax and Taxpayers' Money Argument*

Tax is what a citizen pays as decided by the laws on the subject. It is compulsory payment in the form of financial charge or levy imposed on a citizen or other legal entity by a governmental organisation under a law specific to it. It is not necessary for a government to rationalise taxation unless... The idea behind taxation is subliminally accepted by the public by agreeing to it with or without opposition. Sometimes the opposition can turn violent and ferocious. But by the acceptance of tax laws people may consider it as perceived and the governments may also state the reasons through information media. The acceptance of tax laws is under the supposition that the money will be used by the government for the benefit of the people through various means of governance as part of the cost of governance. The tax thereby is considered to fund the direct and indirect spending of the government which is meant for governance. Government is the taxing authority who levies tax through taxation. Failure to pay tax thus levied by the government is naturally punishable under law. There are various taxes as decided by the government. All these arguments make taxation the decision exclusive to the government.

An out of law argument is that an individual citizen or entity should be paying taxes for the income and other returns acquired wherein free access to national commons were also utilised. National commons belongs to all. National commons is

¹⁵ Sainath, P. (2000). *Everybody loves a good drought: stories from India's poorest districts (20th anniversary edition)*. Penguin India.

public geoproerty. Therefore, there is a moral and ethical contract based on value system of society for paying for the services received for earning income from the national commons proportionately. The tax thereby paid is under a moral code of conduct which taxation formally legalises for public convenience and conformity under the equity and equality principles. It is amended periodically as appreciated by the government based on the needs of governance. Taxation is rule of law, a function of national governance.

The question is whether a taxpayer has any claim on the tax paid. No, they do not. It can be explained.

The assumption that taxation is government taking money from taxpayers and therefore the latter have right over their money and, to check and verify the government spending is worldwide. The people have rights to check the activities of their agents, the governments, even otherwise. It is not because they pay taxes. It is there even for citizens in countries where there is no taxation. The right to audit a government is not decided by the act of paying taxes. It is inherent in the citizens' acceptance of a government by whatever means. It is pseudo thinking that the money paid as tax belong to the taxpayer and is an economic right. Generally people believe and even vociferously argue in public forums and lap up the belief that taxation as the appropriation by government of "our money." The assumption is that the state takes "our money" from us. This makes them argue: we give up what's ours for the greater good of our society. This is in the belief that the taxpayer has some kind of right or entitlement to pretax income. This is not so according to the economic right for which the pretax income is inalienable. This also makes the provision of public service, rule of law and other outcomes of governance the role and functions of a government and therefore the parts SNS and NSS of governance. The government is accountable for governance. If the taxpayers want to involve in deciding how the government should spend the tax collected from them then the accountability of government gets thinly diluted. That any way is not a desirable situation in governance. The desired approach, therefore, is taxation under the law where establishing rule of law is a role of the government.

But the feeling that the pre-tax income is "our money" is difficult to shake off being a perception. The feeling is supported by the belief that the state is taking away from the taxpayers something that belongs to them by their right to own. It is aggravated when they find there are many who are exempted from paying tax and taxation accordingly is partial and discriminatory. Careful reflection will show it is almost universal assumption under human singularity. There is no moral or legal sense in such perception. No one has legal right to his or her pretax income. There is a legal obligation to pay tax as in many other situations under rule of law. But money is a kind of security blanket for humans. Someone pulling it away is naturally resisted. Tax is only one such act. The definition of taxation is clear on that.

It is also hard to conclude there is moral right to pre-tax income for that would imply that the earning by distribution of pre-tax incomes is perfectly just. There is no way to measure it. It is one of the vagaries of the human system governance. Therefore, the government is the best agent to decide on taxation and the people including those in the government are liable to pay it without claiming insensibly

any right over it. There is no taxpayers money. But the lawmakers and enforcers too should appreciate it to hit the right balance the rule of taxation laws apropos GBNS.

27.6 Reality of Tradeoffs

Is the opportunity cost real? The reality of tradeoffs, especially in governance, is hidden in this question. The opportunity cost is a kind of a grinding stone to sharpen the chosen alternative or in many cases the only choice that is altered from the previous normal. There is no scientific or mathematical probability for a human to return to what was left once from the new chosen track leaving it. Even then it will be a new one not the one that was left. Hence, in reality, there cannot be an opportunity lost, hence an opportunity cost. This mode of thinking in the perception of opportunity cost, perhaps, is one of the causes of human conflicts and associated miseries. That is against human well-being. The government should be aware of it and so the people. It is better to avoid over-emphasising tradeoffs in governance through a prerogative of governments. But it may take time in human evolution to avoid the concept of opportunity costs and tradeoffs in decision making and discard them as the vestiges of the past in the process of decision making. Till then opportunity costs and tradeoffs will remain.

The term is also used widely in an evolutionary context of life, in which case the processes of natural selection and sexual selection are in reference as the ultimate decision factors. As mentioned, tradeoff is commonly expressed in terms of the opportunity cost of one potential choice, which is the loss of the best available alternative. This term is also prevalent in common jargons such as *nashtartha labham*¹⁶ meaning “losing something may be for a gain.” “The loss is for something better to come” is a directive counselling mode in the human system all over. But the fact is that both the loss and anything that has to come subsequently are real effects of actions.

A tradeoff in government is a process appropriate when it may be in the best interest of governance to consider an action that may involve in diminishing or losing one's quality, quantity, goodwill or property in one way and gaining them in another way by decision to forfeit the previous action for the next feasible choice. In a tradeoff it could also be that when one thing increases another decreases. This could happen in the interactive matrix of national security elements.

There seems to be tradeoffs in nature and social lives too. For example, the more the fecundity (fertility and accordingly the number of children in humans in demography) the less the care children will receive is supposed to be the oft used tradeoff example by governments in demographic security. But this can be used again as a tradeoff in economic security that the poor will have more children than the relatively and comparatively affluent because for them children are income by the

¹⁶A colloquial expression in some of the Indian languages.

possibility of early earning whereas they are expenditure for the affluent adulthood and start earning. This is argued under the marginal income and marginal revenue principle. Again, fecundity matters in some belief systems that advocate more children per family because it helps the spread of the belief system. It is an example of fecundity in social lives. But for governments such tradeoffs should be for careful examination as GBNS is a matter of the ultimate well-being of their people. Interestingly there are also tradeoffs in nature that can beat human tradeoffs in social systems. An example was in the strange behaviour of the river Choluteca in Honduras (Box 27.6).

Box 27.6: The Choluteca Bridge Paradox

The Choluteca River in Honduras is quite mischievous. Because the region gets ravaged by storms and hurricanes. The River plays with the weather just by adjusting and readjusting after every storm surge.

The authorities decided to build a bridge across the Choluteca River in 1996. A Japanese firm built a solid bridge over the river. It was opened to the public in 1998. Soon the engineering marvel became the pride and joy of Choluteca. But within months a hurricane (Mitch) hit Honduras. About 7000 people perished. Rivers swelled and all the bridges were destroyed, except the new Choluteca, though the roads on either ends were swept away. But the worst was the behaviour of the river. It moved away leaving the bridge to stand in isolation as if in a divorce move. This perhaps was the only case in the world where a river left its bridge, which was the pride of the country, adamantly. Perhaps it was jealous of the fame the bridge acquired in a short time.¹⁷

The Choluteca River that flowed separately from the bridge also brings out a paradox in border dispute resolution decisions between countries across rivers. The rivers are expected to change courses and also get displaced laterally. In a disputed river boundary the lateral displacement could be favourable to one and as much unfavourable to the other. Hence the decision for the favourable is to wait and the unfavourable to resolve as early as possible. That is the different tradeoffs the disputed parties can think of. There are no cases of such dispute resolution based on tradeoffs so far in the world.

¹⁷Iyer, P. 'The bridge on the river Choluteca.' Business World, 27 April-10 May 2020. <http://www.businessworld.in/article/The-Bridge-on-the-River-Choluteca/23-08-2020-311912/>. Accessed 20 November 2020.

27.7 Summation

A tradeoff may involve in forfeiting an action for another feasible choice. In a tradeoff one thing increases and other decreases which are considered proportionate by the involved parties but may not be for a third and independent observer. The third-party appreciation of disproportion can often turn into conflicts in a governmental system. This is not easy to identify and appreciate. As a result there are many misconceptions about it in political science. For example, tradeoffs are equated with power gathering through authority and associated income generation under vested interests. This is called corruption in political studies. Corruption and sleaze amounts to abuse of power by those in authority. Power is required to abuse it. Therefore, it is not a tradeoff but an activity sans ethical practices in whichever way people define them. Gathering power is not a tradeoff.

Tradeoffs are important across diverse areas in governance. Understanding tradeoffs call for systematic and involved assessment of the topic in matters of governance. This can be done by the authorities involved as they are part of decision making or decision executing. They will have the feel for it. The people who do not agree with decision making of governments after assessing the tradeoffs may not have the feel for it as they stand as detached observers. Researchers of tradeoffs will have to provide insights into the possibility to balance tradeoffs and strategies.

Tradeoffs for a government can be a decision advantage on one hand or a loss making proposition on the other. There can be many alternatives. For example in a limited fund situation a government may face serious tradeoff dilemma on allocation of funds. Appropriation of fund for one project may have associated reduction in another. Under such situation some governments may go for loan or other fundraising programmes that could so result in serious tradeoff situation in which the outcomes need not be fully encouraging. The tradeoffs in governments are perennial and a major part in decision making demanding serious involvement of professionalism in governance. Tradeoffs appear in every element of national security decision making and need not be based on money and finance alone.

It is generally considered tradeoffs create opportunity cost. This study disregards opportunity cost as an imperative for decision making. The “would have been factor” in all aspects of life and governance is neither a reality nor an abstraction. For this study it is unreal as what is not happened cannot be measured accurately or compared with what happened. So the idea that tradeoffs create opportunity cost is not considered in this chapter on tradeoffs. However, it could be accepted a different method of approach by people who find reason in opportunity cost assessments. The cost is for that which traded off and yielded accordingly in reality assessment. The opportunity cost is the cost of what is not chosen. In his study what is not chosen dissolves within what is chosen. This is a deviant in national security studies that has been considered appropriate.

Another aspect is the concept of welfare state which according to this study is a temporary model of a social system to tide over the war and post war depression baptised by the Beveridge Report of 1942. It was UK specific. The continued use of

the term in many political expressions, therefore, doesn't hold water especially in GBNS which is meant for all the nations that too in an advanced world when wars of such magnitude are never possible unless human beings turn to extreme barbarism in modern garb. Reverse evolution is not even a rare possibility.

28.1 Introduction

Surprisingly, there are no centres or similar facilities in the world carrying out exclusive research in the wholesome or integrated concept of national security for decision making in governance. What the world deals in the name of national security is physical security of the nation from external and internal threats along

with economics and other vital faculties as the governments find required in support of governance to make the nation a safety citadel. Great walls and fortresses are examples for this conviction (Box 28.1).

Box 28.1: Hirkani and the Raigad Fort

The old fort at Raigad, Maharashtra, India, was the symbol of power and security to the Maratha Empire ruled by Chhatrapathi Shivaji (1630–1680).¹ An interesting episode associated with the tales of his life was his encounter with an ordinary milkmaid who lived near the fort in the village. Her husband was a soldier in the emperor's force, most of the time away on military grounds. One day the lady got stuck in the fort after supplying milk. It was sunset time and the guards locked the gate for security reasons as per the rule. Her pleading to the guards went unheeded. She was told to stay back and leave at sunrise. She was restless at the thought of her baby crying of hunger though there was an elderly lady from the village babysitting. Then she did only what a mother could do. She scaled down from the steepest side of the fort, where there was no protective wall being a vertical precipice, hiding from the security guards as well as the nocturnal wild animals and reached home past midnight. She breastfed the baby forgetting the ordeals she had gone through by then. Though a serious crime, leading to suspicion that she was a spy, the wise Emperor understood her plight listening to her. He knew mothers didn't lie. He not only honoured her with the title "Hirkani (small diamond) but also named the cliff side wall that he braced later, "Hirkani *Buruj* (Bastion)". The Hirkani bastion still stands there as an ode to all mothers.

And the tale also tells that human well-being is a feeling and that is not just physical security and relative luxury. Well-being is strictly an individual stasis. The king has to provide it to the people for their acceptance and approval to govern them, even if under submission.

Governing to maximise national security to enhance the well-being of people is the function of any government. One of the reasons for this stasis in governance is that the concept of national security is not clearly understood as it is still evolving and may even acquire other names in course of time. And, even if understood, it is not the priority of governance as tradeoffs matter seriously in human survival behaviour patterns that are fixated at the moment. Research, therefore, is carried out in niches of situational convenience and the results that a government may become privy to will be a collage of multiple researches in the name of perspective national security. This makes the concept of national security an ever-ongoing hypothesis for the reasons, (1) it is evolving, therefore alters along the timeline, and (2) the changing nature of human perception about security makes national governance a perceptive abstraction denying humans a universal format for human

¹ Shivaji Bhonsale I formed the genesis of the Maratha Empire in 1674.

system governance. Governance therefore provides many choices in process to governments. It is an advantage in one way. But this study about the concept of national security recommends retaining the identified end objective, human well-being, as the common goal for all forms of governance in its abstractive perception which again does not have a fixed goal post being a reverse moving target. Well-being as the universal end objective or common goal can maximise the result of governance. The present stasis causes serious impediments in national governance on one hand but on the other governments have multiple choices for the process of governance. That is why every government in the world has its own signature format for governance even in the same country.

Notwithstanding the projected stasis of the concept, research in national security is similar to any other research for knowledge generation, acquisition, retention, distribution and regeneration from the findings for the benefit of the global human system. In national security, it is a kind of intellectual exploration and incisive rummaging of data in the human system environment to gather information and, thereby, knowledge which could benefit national governance for the advancement of the system as a whole. It is vital for competitive governance to ensure the well-being of the people as far as possible. The research has to be continuous as the findings can be short-lived since the concept turns back to a hypothesis even after testing and finding acceptable. That is why research is important in national security and the interesting point is that it can be done anywhere the government is active during all kinds of governance interventions.

Well-being of the people is the prime objective of national governance according to the national security concept. The role of government is based on governance. It is subliminally embedded in the constitution of every nation. But there are practical difficulties in achieving exactness in human well-being. Or that is what the governments think. The concept of well-being is a deep-rooted behavioural aspect in humans. A government can provide well-being to its people. It has the authority. A state is the most powerful human system. It is more powerful than any individual or group in the system.² The state has the authority and wherewithal to research and experiment in national security subjects. There are many reasons why a government land short in this primary task. The reasons are not exclusively political as critics of governments may project often. These factors come under the two critical laws of human system brought up earlier—law of invariance and law of limitations. These laws stand exclusive from each other. They are totally disconnected. Law of invariance comes from the fact that humans cannot perceive changes, if part of the change, when it happens or for a considerable time after it happens.³ So they perceive history repeating or past is keeping up with them. Human intellect is not

²This is the lemma based on which a serious student of geopolitics may examine the systems where ideologies rule nations or, rather, the nation is secondary to a group. It is an unstable situation according to this statement.

³The study of calculus as a mathematical faculty has something to do with this intellectual blankness.

developed to that level though it is not subhuman as someone said sardonically. It is also possible that observation of life system change can be destabilising to the momentary present that should not be felt to maintain system balance. It is the reality. Simply put, change occurs all the time but humans cannot perceive it at the time of occurrence as if it is a law of survival especially if one is in it. This law will be visible to an incisive observant whenever there is talk about the “new normals” kind.

Limitations are constraints in the process of survival. They are plenty. All these needs separate studies and research to appreciate a situation and move forward in governance. It is “good news” that life is dynamic; “no news” if it is static or stagnant. Fortunately it is the former. Fatigue (physical and mental), boredom and monotony would have taken over the survival pangs if it was the latter. Covid syndrome⁴ shows static pangs at some places and in some systems. Life can never be arrested or static. This study looks beyond Toynbee’s arrested civilisations (Chap. 1). It is simply not possible in a human system in modern times. Governments should know. Every government is dynamic with respect to its people, but may not be competitive unless it deliberately and strategically notches up competition. Therefore, research in governance and associated problems should be viewed beyond politics and political systems.

There is no shortcut in governance. Every style and form of governance follows its natural frequency. Proceeding under the natural frequency of governance appropriate to the governance system will be safe for the government as well as the governed. Still, a government can induce pressing momentum in the human system to make it dynamic and turn the life of the governed towards the better. The government has the potential to provide them better lives without discrimination. Governance can be tuned to make citizens feel better and better every day in their individual as well as social status. It is not an idealistic viewpoint, but a pragmatic objective. It is a process in the advancement of quality life by techno-economical changes and knowledge in a society. The world is better today than it was yesterday. It should be better tomorrow, naturally in a linear mod of advancement. That is also called sustainability. It is necessary to make future generations comfortable. That is the way to carry forward the well-being created by governance. The world should be better tomorrow than today since it is better today than yesterday. This falls under the law of invariance when expanded. But the pace of such evolution will be relatively slow and can be accelerated by effective governance to balance quality with rising demography. The pace of governance can be advanced by acceptance of the principles of national security and understanding its importance to people and governing it towards maximisation so that generations can be benefited by the results earlier than by the simple linear process with staccato overwriting of evolutionary streaming. Governance can provide guided steering rather than unguided drifting.

The world has never experimented seriously with a positive and pragmatic intent in finding ways to achieve NS_{max} . It is obvious from the trauma, agony and fear that

⁴The forced change in human life system globally in the pandemic situation caused by Covid19.

prevailed in the past as history recorded them and continues to infuse the world over. The whine of agony that emanates from various quarters of the world is audible to those who listen with awareness. The people of the world are yet to get the care that they rightfully deserve from those who govern them. They need it more than ever in the centuries ahead as demographic inkblot spreads further. The world may be uncertain, but quality life can be provided to the people by sheer governance. Governments are meant for that. Peoples' participation is another point. Every life is precious and, at the same time, extremely short. The objective is to improve its state at all times. There are ways and means of doing it. Governance has to be people-centric.

Theoretically, the methodology of governing a nation should be uniform the world over. But, it is not so. It depends upon the national perception of governance and human well-being. The binary polarity of the global human system based on power on one axis and faith on the other influences the geopolitical entities of the world and the humans within them. The well-being too is subject to the flux between the polarities and their interactions. Inside the realms of national security, spiritual security fills up the void left by apparent security. Theoretically, a government is right when it prepares for maximising apparent security as in many countries. But it leaves a void inducing pressure on citizens. The people feel the brunt of the void in their lives as the way they are positioned within the two axes of the binary polarity that divides the system. The proximity and proprioception of the polarity decides the feeling of well-being. As it varies from people to people, governments too find it difficult to provide uniform well-being. This becomes complicated as apparent security and perceived security stand inseparably intertwined. The governments therefore cannot separate perceived security factor while governing by national security.

The concept of national security is enlarged to the perimeter of nations. The concept, with certain modifications, can be applied effectively to other formal groups: organisations, corporates, business houses, families, etc. It is a kind of "strategy transfer" from national security strategy to the smaller organisations if they so desire. This will call for a separate study. This is also the advantage of research in national security. The models obtained through research can be used for other similar but smaller organisations within the system. While maximising national security is by proper governance, it is by objective management and micro governance in smaller groups. National security maximisation by governments calls for macro governance.

28.2 Purpose of Research in National Security Governance

Research is for knowledge generation, acquisition, retention, distribution and regeneration. Knowledge is essential for human development. The knowledge created by research can be applied to better the systems humans live in. Or that is what is expected out of knowledge process. National security governance means governing

to maximise national security, NS_{max} . It needs research at all levels because serious decisions are to be made. Research is a thinking game; it is logical reasoning to find the truth from facts. It involves the micro perspective of the spot decision making to the macro perspective of governance and instant measured decision matrix. The primary need for research in the concept of national security arises from the way the topic has been projected in this book.⁵

Research is a continuous process. The subject of governance is highly practical. There are many scholarly and expert knowledge executives in the government and its agencies engaged in its actualisation who can research concurrently with governance as part of SNS and activity of NSS.

The need for research is embedded in the demand for quality life by the citizens. The citizens are the ultimate stakeholders of governance. The purpose of research is justified by the needs of the stakeholders. The accountability of national governance is with the government. The knowledge gaps can be filled by research. The research should lead to building networks of executors and thinkers, and open waypoints and lanes for dialogue, reflection and analysis.

National security, as defined in this study, is the penultimate goal of governance of the nation. The target will move away in the attempt to achieve it because of human vicissitudes in the appreciation of well-being which fluctuates at any particular time. Therefore, the only possibility is maximising well-being, at least for now and the immediate future. Since the goal is a moving variable and indefinite, the approach paths will be different for different governments. Since governance is a long-term strategic application of activities based on policies and processes, there is no definite path. Hence it calls for continuous research and logical examination at every step towards it. If the goal was a definite and approachable destination like a target to shoot at, the track towards it would have been known and standardised for each country in which case serious and continuing research would not have been required. This statement is hypothetical, though.

Research is required to know the unknown. The steps towards the perceived human well-being in the national security context but unattainable in absoluteness and also varying every time should be charted and recharted. The destination is dynamically engaged in hunting for precision stability and moving all the time. The reasons for hunting of the destination include its timeless limit, indefiniteness, competitive build up of nations, absence of a globally authoritative government for centralised global security rather than collective security, personality traits in the human systems, and many others. Hence every step taken by the governments has to be studied in detail. That means every decision has to be considered to establish accountability and measure effectiveness and calculate efficiency. Such decisions can be arrived at only after serious research. Hence, research becomes an inseparable part of national security governance which will be specific to each geopolitical entity. In this study the effort is to provide a thinking platform to national decision

⁵Paleri, P. (2002). "The concept of national security and a maritime model for India." *Doctoral dissertation*. Department of defence and strategic studies, University of Madras, India.

makers in appreciating national security as a unified concept of well-being. Considering that well-being cannot be clearly defined the nations can vacillate on it as desired by them in relative terms applicable to the prevailing belief systems of their people. But the concept is suggested to be kept uniform the world over as it will help to assess comparatively to appreciate their relative positions in national security. Presently there is no such system. Every existing system for relative assessment of nations is hypothetical. An example is relative comparison of nations in terms of happiness which is a varying emotion and hence abstract for physical or statistical measure for comparison.

Recommending research in national security is from the basic assumption that the concept is practical, not a fantasy objective. The objective of research is to enhance the practicality and viability of the concept in national governance and not simply on theoretical aspects for the sake of knowledge. At the end of it, the concept has to be implemented on ground by governments. The findings of research should be value-based addition towards the efforts already on in enhancing national security. Summing up the topics of research in national security, though will always remain an unfinished task, is prepared primarily to ignite the mind of the strategically inclined. The primary research areas are categorised further.

The purpose of research is to find the ways to reach the destination at the end of it all. But what if the destination is not clear?

28.3 Anatomy of Destinations

The destination should be clear before planning the passage. While the purpose of research is to find ways to reach the destination, the primary aspect prior to research is to decide whether the goal identified is a destination and, if so, the type and nature of it. This is where one has to see the reality or factuality of the destination. A political party may bring it in its election manifesto and promise to the people. The people should be able to analyse whether it is a destination that is pragmatic and acceptable to them. Otherwise they will be espousing the false promise. From simple pacifying words of a doctor that “the cancer is in early stage; we can cure it” to a fundamentally incriminating comment that the “whole world will be brought to follow my God that can lick yours” can never be accepted in the normal sense, but people lap it up keeping governance null and void defying psychological contracts⁶

⁶Psychological contract is a concept devised by organisational scholar and researcher Denise Rousseau. It represents the mutual beliefs, perceptions and informal obligations between an employer and an employee. This is an interesting term that the author had applied in relation to sexual harassment in a major corporation that ultimately resulted in the victims feeling of let down by the organisation that made her leave it which is a reverse let down of the organisation by a competent member because of an obnoxious employee whom the victim identified with the organisation being senior. Regrettably the legal aspect of such breach of psychological contract had no applicability in gaining the self-esteem for the victim. It is not known how the offender (the

between the governed and the governing who represents the state in the eyes of the former (Box 28.2).

Box 28.2: Psychological Contract in Citizen-Nation Relationship

Psychological contract between a nation and its citizen is the way they are interactive mutually by responding to each others' needs. The nation for a citizen is what it gives him or her identity and not the other way round. Nation is more important than its people but there cannot be a nation without people. It has been also mentioned earlier a nation needs land too to be called a nation. People alone cannot make it governable. The people represent the nation. There is no place for deceit in this relationship. The government or its agencies represent the nation as the other party of the psychological contract. They too are citizens, hence subject to the social contract. People develop aversion to their nations by the assumed breach of contract when the government is indifferent to them. Hence an important role that is embedded in governmental functions is to remain as the custodian of the psychological contract of the citizens with the nation, the entity. The terms associated with the psychological contract are patriotism, nationalism and so on as often referred to, which doesn't carry much weightage as metrics for the level of psychological contract at any particular time between the nation and its citizen. The role of the nation in the psychological contract with its citizens is to provide them the identity of a citizen. It does it in many ways. The ceremonies associated with the grant of citizenship to immigrants and settlers in some countries are symbolic of this role of the nation, performed by its representatives in the government.

A firm and pragmatic destination in governance can bring out the truth from facts. It means people have to be aware of the goal of governance. In case people are not aware, the governing, that means the government, should be conscious of ethical governance. That is an ideal situation in wishful thinking. It is not easy to make it possible under vacillating human nature. That is another reason for identifying clear destinations in governance.

In this explanation, destination is the goal, the end objective. It is the target. So, unless the destination is clear the threat to the target cannot be appreciated. The anatomy of destination, therefore, reflects the threat attractiveness of the target. The destination in national security is never reachable. It is a moving horizon. It has been examined earlier. There is no clear definition for well-being in national security as an achievable reachable totem pole or summit peak. This is a situation of convenience and advantage in embracing the concept of national security in governance. The idea

harasser) felt subsequently. The term used by the scholar in organisation research can be applied between a nation and its citizen (see box). Paleri, P. (2020). *Corporate social responsibility: concept, cases and trends*. Cengage Learning Indi Private Limited. p.140

of well-being is a kind of Catch 22 destination; it is there, but not there, when it is there. Clarity of destination in uncertainty is what gives national governance the necessary freedom to manoeuvre in national security governance. The governments can modify the style of governance and maximise the result which also provides the necessary differentiability to the product or result. The maximisation process not only becomes relative to the government, but also makes different governments comparable relatively by indexing. This makes national security an attractive concept in comparative analysis of human systems and generating competitions among them for the overall benefits of humans by forward movement. A definite destination makes the forward movement static after achievement. It stops there. An indefinite destination makes the process continuous and dynamic. It cannot stop. It suits the process of national governance. There are no holidays in the process of governance process. Yes, there could be slowing down as one can see in a pandemic situation or a major war. Slowing down need not be inefficiency or incompetence, but a process of regeneration and recuperating after a fall that is essential for survival. Slowing down if followed by collapse could be undesirable mostly, though there are desirable collapses in systems, if it triggers more competent regeneration. The destination in national security will have an element of uncertainty that may make it more dynamic.

A fixed goal destination can be attainable totally. A moving destination can keep the process of achieving it in perpetual motion. The latter is more desirable in national governance as the end objective. A nation is ideally a surviving continuum whether the life span is long or short. Therefore, governance needs a destination that is a moving target which is constantly followed. That is the concept of national security with its moving target of human well-being remaining hot all the time. That makes nation driving or governance fun. Well-being as a destination is neither hidden nor unseekable. The seekable destination is the one that is capable of being sought. National security is a seekable destination, but not a dead-end destination or terminal (see further in Sect. 28.5).

28.4 Modelling National Security

Models help in research as well as in decision making post research. But the decision maker should be aware that they are not real. Even a designed prototype is a model that is not for the market. This is the caution that one has to exercise while applying a model to the reality of life in a human system.

Modelling is not about mathematics (maths or math). But mathematical thinking helps to understand models. It is not easy to explain mathematical thinking. It is enough to understand that every human has the ability to think mathematically. It is a beautiful subject or topic of study in abstraction that is necessary for human survival using intellect as the survival tool. Not necessary for other life forms. Under this argument every human has to be proficient in applying maths in thinking process.

Mathematics can target situations and make them flexible and malleable for decision thinking. It is a beautiful subject (Box 28.3). It can fit in perfectly in national security research.

Box 28.3: The Beauty of Maths

Oh, mathematics. . .

The way one can dance with your numbers in theory of numbers,

6174, the Kaprekar constant and its likes,

Constantly thrashing the best of any game in cyber,

Just lounging in numbers,

Feel and experience incremental change in calculus,

Chase the missing clue in algebra,

Appreciate shapes and forms in geometry,

Fantasise undulating curves in spherical trigonometry,

Put to game interactive entities in determinants,

Assimilate the foibles of chance in probability,

Stretch out for a mental workout in topography,

Make it chancy by farming in time,

And more. . . and more. . .and more. . .

Oh, mathematics—only you can enliven an old brain young. . .

The beauty of maths lies in its wavering abstractness (now it is, now it is not) as the centre line of human reasoning. One side is what one calls science and the other side is arts (for explanation only). They are two different ways of thinking that the dividing mathematical brain allows to leach into each other on and off. It is possible for humans (only). There is order in (almost)⁷ everything about mathematics. It can even review a disorder in an orderly manner. A simple statement in mathematics can explain a complicated subject of life in less than a single line. Look at the statement by a cartoon character, “*a square is a circle that is trying to go straight*”.⁸ It is a statement that hits straight, though the punch is in a humorous wane. Everyone knows that a circle cannot become a square even if it is highly influential with connections at the top. But they may both look alike when they are reduced to the minimum size visible to the eye—a dot. But, still, a square peg won’t fit well in a round hole. (Does it talk about leadership in governance?). Then, there is this naughty figure that can never agree with its value embedded in the genes of a circle— π , 3.141592653... It makes its appearance in mathematics in a handsomely

⁷The author has slight problem with zero. It is not yet clear whether zeros is a number. The author considers it a number of convenience for humans to crossover stumbling blocks in calculation like the age of earth for example. Just place a lot of zeros on the right will solve the problem and so is in using the terms to modify precision statements. Brahmagupta (598–668) gave the rules to compute with zero but was stuck in clarity of division with zero. He formalised the arithmetic operations of zero though I was invented by Mayans in 4. Also see Chap. 3.

⁸Hart, J. “BC.” Cartoon strip, *The Asian Age*, New Delhi. 6 October 2004. p. 18.

adopted Greek body— Π , the sixteenth letter of the Greek alphabet. Pi is a never-ending quest to know itself. Mathematics is not life; life revolves around it. Mathematical expressions can be used in explaining many concepts in a better perspective. National security is one such concept. Care is to be taken while explaining them mathematically so that it is also understood by people who are not inclined to mathematics. Most of them are not inclined. They too have beautiful minds. Here lies the most critical part of modelling national security. The models, especially those based on practical applications should be projected without the complexity of mathematics so that it is acceptable to everybody in the game. But one can always appreciate the beauty of maths whether inclined or otherwise.

National security, being a variable and measurable quantity, is a function of time. Modelling national security starts with it. The model visualises the subject as a function of time because the process is a vector, not a scalar (quantity) for explanation. That means it has a direction. And the direction is in time. Once released from its static inertia, it moves forward and backward oscillating dynamically (surging) depending upon the national security index in time. Time is irreversible. And so is the good old entropy.⁹ (There is a connection here though not relevant at this stage.) Today the concept of national security is in a state of static inertia (called a limbo at times, though not exactly the same) in many nations of the world. The concept has no momentum in such state. Wherever introduced in a limited fashion, the subject is gaining momentum, thereby breaking the static inertia and getting on with dynamic inertia.

28.5 National Security—Moving Destination

It is simple maths. Under this lemma, that the concept is a dynamic vector in motion, it is necessary to presume that the concept when integrated from zero to infinity will aim at maximisation of national security in a country. The ultimate objective, therefore, is to maximise national security. The target could be depicted by a symbol. For the sake of convenience, and to avoid complications in its comprehension, it is symbolised in a non-mathematical form as,

$$NS_{\max}$$

The objective of a nation is to achieve the ultimate in national security by governance, which is equal to NS_{\max} . It can be integrated into the form:

⁹Explained further in Chap. 25.

$$\int_0^{\infty} NS \, d_{ns}$$

It is further equal to the sum total of the optimised value of each element. It is necessary to know that the optimised value of an element is different from its maximal value. It has to be arrived at taking into consideration the gain in the interactive value of each element with another. Because an incremental increase in one can cause a decline in another in some interaction. In other words, the fact that the efforts of maximisation of one element (say, military security) did not cause a change in another element (say, in economic security) by decline larger than the former means that the total change in NS_{\max} is positive (incremental). It is the total make up of national security factor that has to be prevented from decline by the interactive gains and losses of elements. In such case the quantum of national security is equal to,

$$NS = \sum NS_{\text{elements}}$$

whereas,

$$NS_{\max} \text{ need not be equal to } \left(\sum NS_{\text{elements}} \right)_{\max},$$

unless all the elements are positively changed by an incremental change in their interactive element. Normally the change in the quantum of national security will be the resultant of changes in the interactive elemental matrix.

A slightly modified explanation, under such circumstances, is to identify the value of the elements at a particular stage through which the national security matrix of a country at that stage can be derived. This can be achieved by giving the elements certain values before calculation. To give them values is not possible unless specific studies are undertaken. The elements can be symbolised (again to avoid serious mathematical imbroglio in understanding the subject) alphabetically. A symbolic assessment of currently identified national security elements is given in Table 28.1. Symbols are allocated to the elements for identity while assessing their quantum in mathematical modelling and calculation of national security index at any given time. They are variables. Values can be assigned to them according to situation appraisal.

The “quantum” value of elements will be the prime parameter in decision making in national security matters. National security of a nation can be enhanced effectively by managing its elements with due consideration to its effects on other elements. These elements can be brought under a matrix to project the national security matrix for decision making. It will be then:

Table 28.1 Symbolic representation of national security elements

	Elements of national security	Short title	Symbol
1	Military security	Milsec	m _{s1}
2	Economic security	Econosec	e _{s1}
3	Resource security	Resourcesec	r _s
4	Border security	Bordersec	b _s
5	Demographic security	Demosec	d _{s1}
6	Disaster security	Disastersec	d _{s2}
7	Energy security	Energysec	e _{s3}
8	Geostrategic security	Geosec	g _{s1}
9	Informational security	Infosec	i _s
10	Food security	Foodsec	f _s
11	Health security	Healthsec	h _s
12	Ethnic security	Ethnicsec	e _{s3}
13	Environmental security	Envirosec	e _{s4}
14	Cyber security	Cybersec	c _s
15	Genomic security	Genosec	g _{s2}
16	Microbiomic security	Microbiosec	m _{s2}

$$NS = \begin{pmatrix} m_{s1} & e_{s1} & r_s & b_s \\ d_{s1} & d_{s2} & e_{s2} & g_{s1} \\ i_s & f_s & h_s & e_{s3} \\ e_{s4} & c_s & g_{s2} & m_{s2} \end{pmatrix}$$

Symbols representing the 16 elements of national security are arranged in a rectangular 4x4 matrix (four rows and four columns), which could be compared with other matrices in a finer assessment of interactive dynamics. Such matrices could be either that of terrain-based security matrices or elemental matrices as required. For example, a holistic view of maritime security matrix, a constituent part of national security, could be analysed with respect to the national security strategy in a model exercise. This concept, it is believed, can lead to models based on mathematical design that can support the calculation of the NSI, the national security index. The elements can be a set of natural numbers (N), integers (Z), real numbers (R) or complex numbers (C) according to calculation for the purpose of modelling.

The matrix will change when there are additions or deletions—whenever a new element comes up, or an existing one is taken off and thereby loses value. For example, if the world 1 day decides that the concept of military campaigns is outdated (that will be a day of earnest promise!), there will be no more wars. The military security element may either disappear or disintegrate into more than one, making it difficult to make a geometric array. If the element fades away, the number will be reduced to 15. In such case the matrix could still incorporate the element of military security as in the past, but its value will be null for calculations. When the increment in elements reaches to 17 there will be at least one null element as a dummy to make an array of 18. This is not likely to happen in the near future as even

the 16th element in this study is new and is yet to be taken up seriously by governments to bring groundbreaking policy changes in governance. Such arrangements provide excellent flexibility. The rows and columns may have extra elemental space(s) filled by null elements that are dummies. It will be advisable to place minimum dummy elements for a comfortable matrix for calculations.

28.6 Interactive Matrix of Elements

The interactive arrangement of the identified elements of national security has been made in arrays (horizontally in rows) in sequence of their assumed hierarchy. It is only for the sake of convenience of model building. The hierarchical qualities with respect to the presumed time of introduction of these elements have no (serious) significance in NS_{max} .¹⁰ It is the interactive geometry that is important. The elements, therefore, can be arranged in arrays as convenient.

It will be better if the null element in such case is positioned in the space occupied by the element in the table. In case a new element is introduced, the null element or elements could be placed at the end of the table after it. The table of elements provides the background for the national security matrix as well as explaining its interactive geometry.

An array of the 16 identified elements and their accepted symbols are given in Fig. 28.1 for quick reference. This array is also given in Chap. 6, the elements for convenience.

1 Military security (Milsec) (m_{s1})	2 Economic security (Econosec) (e_{s1})	3 Resource security (Resourcesec) (r_s)	4 Border security (Bordersec) (b_s)
5 Demographic security (Demosec) (d_{s1})	6 Disaster security (Disastersec) (d_{s2})	7 Energy security (Energysec) (e_{s2})	8 Geostrategic security (Geosec) (g_{s1})
9 Informational security (Infosec) (i_s)	10 Food security (Foodsec) (f_s)	11 Health security (Healthsec) (h_s)	12 Ethnic security (Ethnicsec) (e_{s3})
23 Environmental security (Envirosec) (e_{s4})	14 Cyber security (Cybersec) (c_s)	15 Genomic security (Genomicsec) (g_{s2})	16 Microbiomic security (Microbiomicsec) (m_{s2})

Fig. 28.1 Array of elements of national security (repeat from Chap. 6 for quick reference)

¹⁰The period of introduction of the element could find some importance with respect to method inertia. The earlier the introduction, the more the method inertia. Method inertia prevents implementation of new thoughts and ideas and resists change. That is why military security, the earliest known element, is hard and bonded with national security. Recommendations to dilute its importance will be vehemently opposed.

The objective in national security is achieving NS_{max} . Hypothetically it means maximising each of its elements. But there will be situations when maximising one can bring a reduction in another. In such cases the objective will be optimising both. It is very intricate, especially when more than one element is involved in the combination game. It is the most difficult part of managing national security and often riddled with political and bureaucratic conflicts in governance. In a hypothetical situation statement, an incremental change in milsec may:

- Either increase or decrease econosec, energysec, ethnicsec. . . .
- Decrease envirosec, resourcesec, demosec, healthsec, disastersec, foodsec, geosec. . . .
- Increase bordersec, infosec, cybersec. . . .
- Have null¹¹ effect in genosec. . . .

The first step in understanding the interactive matrix of elements is to appreciate that an increment in one element may produce one of the four strategic application points as per situation:

1. **Duality.** A situation in which there is a probability for an improvement in one case and a decline in another.
2. **Singularity positive** (also singularity plus). A situation where the probability is for improvement in both. This is possible though not standard.
3. **Singularity negative** (also singularity minus). A situation where the probability is for decline in both.
4. **Nullity.** A situation where, seemingly, there is no substantial effect. This is quite rare.

In the above case, milsec is the primary element whose incremental change is compared with the corresponding effect in another element—the secondary element. The reaction can be in four different ways. It is important to know that it is not reciprocal—that is when the role is reversed. When the secondary element becomes the primary element and an incremental change in it is considered and examined with the corresponding change in others, the result need not be exactly the same as what it had when the elements were reversed. For example, when an incremental change in milsec brings a corresponding proportional decline in econosec, in the opposite case, an incremental change in econosec may have an effect on milsec that may be progressive. There are countries where improvement in milsec also improved econosec. Therefore, each element has to be seen as primary as well as secondary at different times for different applications of strategy.

This way each element theoretically will have minimum 15 interactions in their primary roles with other elements for every task in strategic application provided the time factor is considered negligible (which is not). There could be thousands of tasks

¹¹ Considering the characteristics of elements, a null effect is impossible. A change in one will have its impact on another. The nullity is from hypothetical point of view as well as for reasons that a change that is negligible could be considered as null in mathematical application.

in strategic application that has an impact on each element in its primary capacity and a corresponding four ways (duality, singularity plus, singularity minus or nullity) change in each other element in secondary capacity. It means there will be 240 possible interactions (15 times 16) among elements at the minimum for each task. It is considered minimum since there are more interactions of primary elements with secondary elements in more than one combination. For example, an incremental change in milsec can affect econosec and geosec together negatively. An example is a nuclear intention by an underdeveloped country. The decision has to be weighed accordingly. It is important to understand here that it is the incremental change that matters in NS_{max} and not decline since the objective is the process of maximisation and not minimisation.

The interactive matrix of national security elements is a complex game. It is for this reason that such approach is not generally favoured by those who govern. It needs highest degree of coordination and understanding which often is not easy to come by under bureaucratic conflicts. The usual way national security governance is carried out is by following the path of least effort. There are many such paths—politically oriented (political party manifest...), faith oriented (canonical inscriptions...) bureaucratic (bureaucratic comfort or conflict...), terrain based (ocean policy, space law...), doctrine based (military doctrine...), internationally oriented (law and treaty...), directives (sanctions...), globalised (UN mandates...), integrated (joint doctrine...) and so on. Managing national security governance by elemental interactive matrix is complicated and needs highest degree of professional competence. Once mastered and implemented, it could be the easy way to NS_{max} . No other method realistically paves way to NS_{max} .

The net result in the process of maximisation of national security will be the sum of increments and decline in each of the elements in its primary and secondary role for every task of strategic application. The results consequent to the application of strategic tasks may not stop at the four points already identified. It can be more. Each of these elements when they increase in their status can cause another four situation application points. This means 16 elements can ultimately cause a maximum of (16x4) 64 application points in their interactive geometry. Out of these, many may seem to be common for one application and uncommon for another. In practice, it may not be so. That means for each action with respect to a particular element, there could be four more application points. Here the application of the task related to improvement of a particular element is important. Each task, therefore, has to be seen as with four application points in each element. The case that an incremental change in milsec brings an incremental change in econosec is different from an incremental change in econosec brings and incremental change in milsec. These combinations, therefore, have to be examined very carefully by the planners of national security. And such planning has to be done before the application of a particular task for maximising the element. Often, it is difficult. Therefore, the planners will have to depend upon national security strategists who, in turn, have to depend upon model-based calculations. Fortunately, the most cost-effective and live modelling can be done using biomodels (BM) in many parts of the world as and when such models

unfold. The bad news is that, in national security, many insomniacs believe in somnambulism. They sleepwalk while awake.

Defining the problem related to national security involves identifying the concerned elements and associated deficiency in it. It is better done by considering each element as a system and then configuring the systems effectively. Problems will appear in an imprecise manner initially. Refining the problems to arrive at the actual issues is the process of diagnostics that separate the symptoms from disease. Otherwise the planners and strategists will end up finding a solution for a wrong problem. It often happens. The result is more damaging to the objective of NS_{max} . These are to be seen by decision makers. The art of decision making is explained later in this chapter.

28.7 Interactive Matrix of Terrains and Elements

The 16 elements of national security have to interact not only among themselves being mutually inclusive, but also with the terrains applicable at any point of decision making based on the research or governance problem. This interaction is extremely complex. Most of the governments fail because of the difficulty in appreciating the interactive matrix relative to their nations. Hence it has to be researched on each occasion that will involve identifying the element-terrain specificity. That means appreciating the terrain that is important for the concerned element and how the terrains and elements have to be conjoined and aligned for a particular decision problem. There is no correct answer as national security governance is nation specific. So every nation will have its own interactive matrix for terrain-element interaction. Identifying the interactive matrix will generally comprise the following steps:

1. Concluding the decision problem—the topic of governance on which a decision needs to be taken.
2. Locating the prime element involved in decision.
3. Locating and sequencing other elements that are inclusive (impacted) with the decision problem.
4. Aligning elements strategically.
5. Deciding the primary terrain on which the decision will evolve.
6. Locating and sequencing other terrains involved.
7. Aligning the involved terrains.
8. Aligning the elements with the terrain in a resultant format (aligning the elemental alignment with the terrain alignment).
9. Decision making.
10. Crafting strategy for decision execution and intervention.
11. Feedbacks and applications in continued intervention.

The 11 steps mentioned above are for academic purpose. It is left to the decisions of the governments and its agencies. But each one of them needs research prior to the

application through various methodologies including modelling. Casual approaches will result in reduced yield in governance interventions. Most of the governments make decisions without considering the interactive geometry of the resultant of elemental interaction and terrain interaction. Figure 28.2 is a typical model for the interactive matrix of elements and terrains. Simply put, the governments should know governance is not sheer gut feeling, though intuition is a major ingredient in decision making..

28.8 Modelling Elements and Terrains

It is a matrix, an array, a table, a cluster...no, not exactly; it is an interactive congregation of a set of elements of a concept of human well-being, to be achieved by governance. How could one shape the congregation? It is not easy to model the elements in a permanent fixation since they are to be seen the way they are handled at a particular time for a particular purpose. But the universality of the elements lies in a model that could be seen vividly. The best approach could be to see them in a never-ending chain of matrix against a vast continuum of terrain specificity. This is

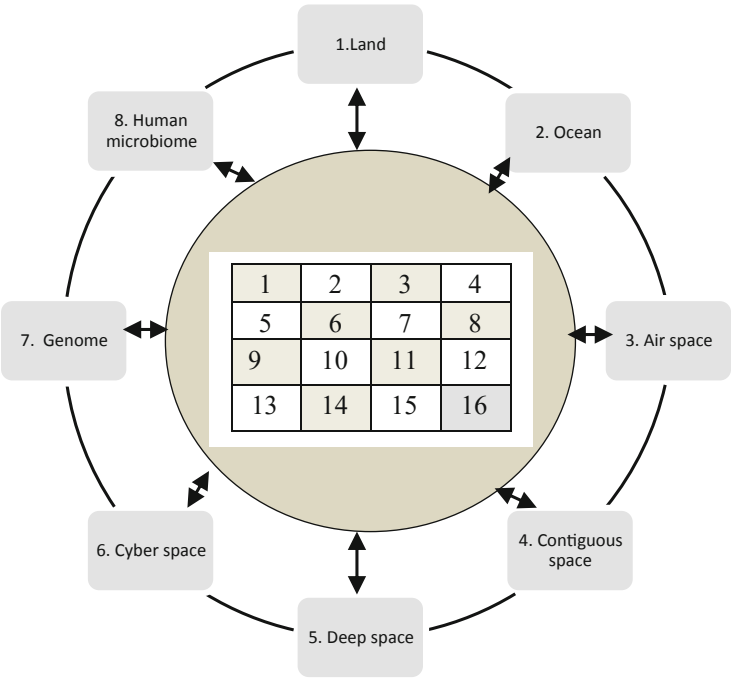

Fig. 28.2 Interactive matrix of elements of national security with terrain specificity for integration of national security

specially so because the target, well-being, cannot be defined clearly as a destination. Pictorially it could be depicted as in Fig. 28.3. Such depiction indicates the never-ending nature of elemental approach to national security in the vastness of the terrains.

28.9 Doctrinal Approach—National Security

A holistic doctrine for strategic appreciation will comprise domains, objectives and goals. Each element of national security needs to be assessed with respect to its doctrine. It leads to realistic assessment of ends, ways and means for achieving the goal thus identified. A doctrine in national security strategy is a body of principles accepted or identified officially and presented thereby. It can transform with respect to changes in the system and system environment. It is not constant. Accordingly, the domains too change. The domain is the area of doctrinal function. It has boundaries that are implied in the statement. Objectives are the intermediary targets on way to achieving the final goal. The goal remains usually committed unless radical changes are imposed. In national security context, the goal is maximisation of national security through optimisation of ways and means with due allowance to the interactive elemental geometry. It is not a definite entity. The basic doctrinal approach is illustrated in Fig. 28.4.

Fig. 28.3 National security elements in the expanding terrain continuum

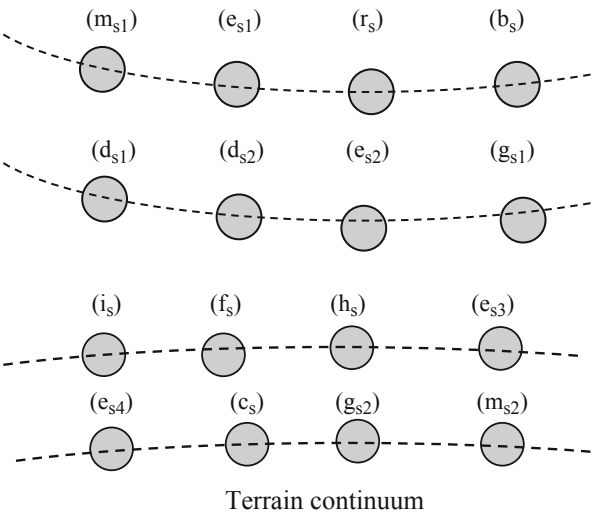

Fig. 28.4 The doctrinal approach

The ultimate goal in national security strategy is NS_{max} . This is achieved through maximising the elements of national security with due concern for their interactive geometry, evolving appropriate doctrines, identifying the objectives and getting there. It is about optimisation. Within each of these elements there will be a domain, objectives and goals. The goals in subordinate elements can be the objective of the macro subject next superior to it. The chain of strategy is very long and has to be extended patiently and carefully. Any mistake in choosing the doctrine will be reflected in the final outcome. That will result in a throw off from the final goal. Therefore, the doctrine has to be befitting to the final objective—the goal. Often a particular government will initiate a doctrine with a goal at the end. Successive governments may change the doctrine with respect to their political environment and ideologies rather than changes induced by time keeping the goal intact. But the result will be a major throw off from the original goal. This is interrupted strategy. It will be ineffective. This can happen to every organisation when there is a change in leadership. The change takes place at the doctrinal level and the goal gets distorted at the end. It may not be so in corporate governance, because the change and ideologies are not going to be interrupted much. This stability in doctrinal approach is that what makes people to opt for privatisation. A governmental organisation will be much cheaper and competitive for ordinary people if it is free from malice of interrupted doctrines and disoriented goals. Unfortunately, that is not the way governance functions in governments and governmental organisations including the forces.

Table 28.2 illustrates doctrinal approach.¹² The goal is the ultimate end result, which is not shown in the diagram because national security is seen as a process here. The doctrine may have more than one domain or a different domain from that of another state. For example, the political doctrine of a state could have political as well as military systems as its domains. In another case, the domain of a nation state based on religion could be different from that of a nation based on secular democracy. The domains may also shift with respect to scenario. A nation under civil war when hit by a monstrous natural disaster may find a shift in its doctrinal domain in a flash. It may shift from the military to the disaster domain in its NS_{max} process. The diagram, therefore, has to be seen only as a hypothetical example. Similarly, there could be multiple objectives for each of the doctrines in the same domain. The strategists when identifying the probable domains may have to see them as nation and scenario specific.

This points out that while nations may have identical doctrines, the objectives and sometimes the domains also could be different. This is an important attribute in geostrategic interactions. An example is given in Table 28.3.

The case of countries A and B are of identical doctrines, but different objectives that will be brewed in different domains. Handling such cases for both the countries

¹²This table is prepared in line with the model given by Navneet Bhushan in his paper, "Future of Warfare: Search for Military Doctrine," published in "Battle Scene in Year 2020," Defence Institute of Psychological Research (Year not mentioned). p. 207.

Table 28.2 Doctrines, domains and objectives: national security—example

Doctrine 	Domain 	Objective (could be)
Political doctrine	Political systems	Avoid war
Military doctrine	Armed forces—Military	Wage war to win
Economic doctrine	and nonmilitary	Support war for alliance
Intelligence doctrine	Military systems	Sustain war
Nuclear doctrine	Economic systems	Increase purchasing power
Biological and chemical doctrine	Political systems	Increase reserves
Space doctrine	Intelligence agencies	Decrease deficit (specific value)
Maritime doctrine	Political systems	Information usage for decision making
Information doctrine	Nuclear policy	Real time information and analysis
Environmental doctrine	Political systems	Deterrence
Resource doctrine	Military systems	Energy
Demographic doctrine	Space policy and plans	Second strike
Health doctrine	Communication policy and plans	Deal with the enemy biological and chemical weapons
Disaster doctrine	Ocean policy and plans	Asymmetrical counter balance
Border doctrine	Political systems	Resource exploration
Energy doctrine	Media	Environmental security
Ethnic doctrine	Terrain specific environment	Intelligence gathering
Food doctrine	Resource based environment	Maritime zone development and exploitation
Geostrategic doctrine	Energy policy	Public awareness and participation in governance
Cyber doctrine	Environment	Public information
Genome doctrine	Foreign policy	Ecosystem balance
	Political system	Resource sustenance
	Demographic system	Energy balance
	Political system	Resource sustenance
	Foreign policy	Energy and strategic mineral availability
	Entry points	Secular attributes
	Political systems	Employment to all
	Social system	Physical health for all
	Agriculture	Psychological health to all
	Diplomacy	Disaster management council
	Internet protocol	Preparedness to support international aid in case of a disaster
	Agriculture	Biometric examination
	Medical	Develop alternate source of energy
		Empowerment of women
		Increase production to a pre-determined target
		Export
		Agreement on cross border confidence building measures
		Dual citizenship to non-resident nationals
		National legislation on copyright violations on net protocol
		Selective modification of food products

(continued)

Table 28.2 (continued)

Doctrine	Domain	
		Objective (could be)

B	Political	Intelligence Military	Wage proxy war against A

will be difficult just by the normally attempted missionary position of negotiation. The missionary position—the often-used soft method for talks across the table with mineral water bottles conspicuously representing each delegate and signatories posing for the photograph without smiling into the camera—may not yield much result in such situations where game theory applications will be called for. It is normally suitable for situations where the doctrine, domain and objectives are identical for the participants. Mostly they are not. These aspects have to be incorporated in strategic mapping for national security.

28.10 Strategic Mapping for National Security

Preparing a strategic assessment of the situation with respect to a particular time or period in a nation’s life is essential for planning a national security strategy for that nation. The purpose of strategic assessment is to guide those involved in national security policy directly or indirectly. It is not a critical assessment of the political system or the policy of the government. Often reality can be unacceptable, but the system has to bear it to steer away like a ship follows weather routing to avoid bad weather at sea. There could be opportunities to seize. In all respects, whether it is a strategic assessment or opinion poll, it is for those who govern to take cognisance or not.

Mapping portrays possible realities and perception of the state about its national security. The mapping should be supported by data projections up to the period the mapping is done. This will be a valuable tool for policy decisions and planning. The types of strategic mapping recommended for developing national security strategy are given below. The agencies engaged will vary.

- (a) ***National Security Policy Statement Mapping (NSPSM)***. NSPSM supports long-term strategic assessment based on national security policy statement of the state. Most of the states may not have a national security policy statement. Such countries work without guidelines, guidelines created by situations or perceived at the time of making a decision. It is a common folly in many countries. What was going on in the minds of the national security agents of Iraq, say a month before the United States attacked them in 2003, or the Indian and Sri Lankan authorities before the 2004 tsunami? Probably they were unaware of the impending calamity. For Iraq, it would have been a situation perceived thinking under a highly centralised leadership. In India, an entire armed force base in an island was wiped out along with its people leaving a few behind to do the last rites. How could one visualise such a calamity? It was worse in Sri Lanka. Behind heartrending pile up of casualties, subjective complacency masqueraded under a waging ethnic conflict lingering on for years. People died since 1986 in the ethnic war that rocked Sri Lanka was estimated to be 60,000. Whereas the toll in the tsunami that lasted a few minutes on that Black Sunday, the day after Christmas, was more than that.¹³ The results are on the ground for the entire world to see and confirm. In the absence of a national security policy statement that is reviewed from time to time, strategic approach to national security will not yield the desired result. There are chances of decisions being incomplete, and actions being guided by misdirected and situated appreciations. Misdirected appreciations provide perfect background for falling to deception in national security, often self-induced. NSPSM is also a tool against deception.
- (b) ***Strategic Area Mapping (SAM)***. SAM supports median planning to maximise returns from certain specific aspects and minimise damage to them. A sample of strategic objective identification by SAM is given in Table 28.4.
- (c) ***Strategic Location Mapping (SLM)***. SLM follows NSPSM. It provides for a fixed long-term planning for operations management in every elemental aspect of national security and does not change for a considerable period. It is based on terrain specificity, threat perception, problem dimension and geopolitical situation against the background of national security statement. Detailed examination

¹³“Sri Lanka Says Its Death Toll in Tsunami Disaster may Top 40,000.” *The Lanka Academic*, Vol. 5, No. 286, 17 January 2005. According to report 30,920 were counted death and 6020 were missing. Bodies were still being received by the disaster agencies at the time of the report. The toll of dead and missing was declared much more in subsequent reports. In March 2005, it was estimated that in Sri Lanka 30,957 were killed, 38,195 were estimated to be dead, 15,686 were injured, 5637 were missing, and 573,000 were displaced.

Table 28.4 Strategic area mapping

Area	Strategic goal
Oceans	Maximise ocean property returns
Resource	Maximise returns
Education	100 per cent literacy
Environment	Maximise returns, minimise damages
Islands	Maximise strategic advantage and returns

of threat perception and analysis of operational archives from available sources are necessary for inputs for SLM zones and areas for maximising national security. Table 28.5 gives a generalised model based on terrain specificity for SLM. Threat perception within this mapping becomes the focal point for operational planning relative to the tasks of the concerned agency.

- (d) **Threat Perception Mapping (TPM).** Mapping with respect to threat perception of the state is for tactical designs and short-term strategic appreciation under varying situations. Threat may vary or shift the location in certain cases. Threat matrix cube explained earlier is an application tool for this purpose.

28.11 Follow on Organograph

The identified model that flows from strategic assessment mapping for national security is given in Fig. 28.5.

National security policy statement forms the basis for decision making. The decisions of the nation's highest body in national security strategy have to be prepared or converted for action. The planners may use various tools including modelling for this purpose and continuously apprise the higher body about the findings and appreciations before they are put into action. Here, SAM, SLM and TPM feedbacks related to the topics are vital. It is churned in shape and actionable decisions are then checked with the higher authority and dispatched to the agencies to execute in action form. It is a simple formula for a very complicated and complex action that may unfold thereafter. Such a model is very essential not only to make national security strategy operationally effective and cost efficient, but also to prevent the people involved from deviating from the desired track in the process. Because, a deviation from the normal by lack of understanding can cause the entire national objectives weary.¹⁴ Another advantage is that, in a conscious governmental system, irrespective of political attributes of the government, the national security

¹⁴“Saddam Feared Iran, not US.” *Hindustan Times*, New Delhi. 8 October 2004, p. 21. An example is the report from the weapons inspector that Saddam Hussein never expected the United States to Attack it (Gulf War II (2003). Throughout, Saddam felt that it would be Iran that would be dangerous to Iraq. Saddam never realised the fixation of the United States on him in its real sense. In fact he was said to be on his way to improve relations with the United States. What happened in Iraq was not deception, but a shift from reality from the perspective of the erstwhile Iraqi ruler.

Table 28.5 Examples of locations for strategic assessment

	Terrain	Examples of locations
1	Land	A village likely to be under drought A coastal area or island likely to be hit by a tsunami A road that could be buried under landslide or avalanche A specific border area that could be infiltrated A mountain range that could be attacked An army outpost A city that is within a disaster zone A nuclear facility More. . .
2	Ocean	A creek where aliens could land An island in the ocean, which could be targeted by militants A coral reef that could be affected by El Niño A fisheries area meant for spawning A sea border where infiltration can take place An offshore area where there are vulnerable oil rigs More. . .
3	Air space	Area within, around and above a particular building A specific border area Air space over offshore vulnerable areas Air space over a military unit Border air space where environmental holocaust can take place Air space close to outer space for missile defence Air port flight approach areas More. . .
4	Contiguous space	Border area for space tourism Neo orbital area Space laboratories Probable spy satellite migration areas Earth surveillance satellite locations Navigational and communication satellite locations More. . .
5	Deep space	Border area for space tourism Neo orbital area Space laboratories Probable spy satellite migration areas Earth surveillance satellite locations Navigational and communication satellite locations More. . .

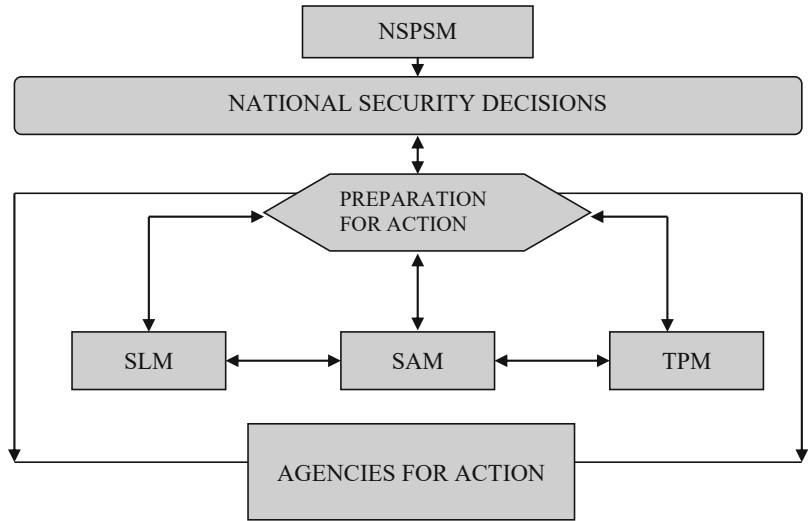

Fig. 28.5 Follow on model—national security strategy

strategy will not shift towards political objectives. The model is generic and can be fractured into smaller models on issue-based assessment.

28.12 Models and Modelling

Models facilitate discernment in decision making as tools. It can only be made once the problem is defined. Decisions can be made without the use of models. But a model can give necessary indications to a close observer if there are errors in defining the problem. If wrongly diagnosed, a careful and experienced decision-maker can make out that there are errors in diagnostics. The structure of the model built on the identified problem will have flaws if the diagnostics are wrong. That is another advantage of model building. Difficulty in making the model may be an indicator that the problem was not diagnosed properly. Models comprise constants and variables relative to the system entity. For example, geostrategic location (geolocation) is a constant for India. It was a variable for Colonial India when the

borders kept changing and governance of the country was based on policies originated in the country of colonial rulers. They were not just one, but also many, whereas Colonial India was one entity. Theoretically, the geostrategic location tends to become a constant when all other parameters are stabilised. The process of geostrategic location moving from a variable to a fixed entity, and then vanishing by disintegration or fragmentation, and transforming into another form, or totally absent, is an interesting study.

Models are used widely. Some are prepared; some are natural. Preparing a model is based on fixed and variable boundaries. There are different types of models depending upon their purposes and functions. The models can be mathematical or non-mathematical. Mathematical models are different because they are represented in mathematical terms—in symbols and expressions. In this book, the objective of national security, which is a very ambiguous term and is based on the perception of the individual that too could be biased on conditioned behaviour with respect to the position occupied by the decision-maker, has been expressed in a non-mathematical symbol NS_{\max} . Here the model is a symbol. Such modelling is simple and serves to guide the decision-makers to converge on to the problem. Such symbols unify the thought process of people involved. There are models beyond symbols for further elaboration of problems with respect to their decision aspects, objective functions, constraints, parameters, sensitivity analysis, etc.

Deriving a solution from a model is based on the procedure developed to test the model. The procedures could be based on computer estimates or under relatively long process of observation, especially in the case of non-mathematical models. In many cases, the models are to be tested, especially mathematical models. Natural models like biomodels (explained later) need not be tested seriously, but corrected for accuracy. Testing a model is highly important when the models are computer-based—programmes, simulation, artificial intelligence, robotics, etc.

All models have two common parameters: scope and details within their boundaries. A quick look at the types of models is given below.

- (a) **Generic Model.** A generic model is static and facilitates planning, arriving at the appropriate options and remoulding with respect to changes.
- (b) **Application Model.** An application model is dynamic and is meant for implementation. It changes with selected option.
- (c) **Driving Model.** A driving model serves as a prime mover to the generic and application models.
- (d) **Simulation Model.** A simulation model is a tool for experimenting with a real system to determine how it will behave to changes in its structure, environment or underlying assumptions.

28.13 About Biomodel

Biomodel in the present context is a standard model which is used commonly for decision making in a live human system. It could be using a dummy body model to establish a murder crime or a social model where a sample test is conducted to forecast sales in a market survey or to forecast election results by psephologists and news media. Biomodels are good for national security research provided they are carried out scientifically and professionally. Biomodels suggested in this study in national security studies are slightly different. They involve identical micro human systems. The micro systems represent a similar macro system if amplified. A test on the micro system could help to appreciate a result or outcome of an intervention or a task of governance much ahead of the planned interventional activity. Military exercises replicating a war scenario can be taken as a biomodel though not all of them are. Most of them may help in honing preparedness level. They may not establish the actual result forecast in case of a war. In some countries there will be a parallel military set up where the military behave exactly similar to the adversary. The parallel force simulates the adversarial force all the time. But it is doubly expensive and many of them won't function as a true biomodel. For example the reality of death or killing cannot be established. It is necessary for many other governance decisions. One is to understand the shift in public opinion. Military exercises may help to know the strength and weaknesses of own forces to some extent. It won't help to appreciate the expected fog and friction in real time. Countries who may not have the wherewithal to establish an enemy force may do it by dividing own forces for the period of exercise as own and enemy forces. But in the latter the enemy force may lack the feel, though it may serve the purpose in a more cost effective way. Past experiences and realistic case studies can also serve as biomodels. But all of them lack the reality touch when studied for the future events and occurrences.

The absolute biomodel is a micro system that may replicate or stand in for the target macro system. Anything that happens to the biomodel micro system may give fairly good information about the macro system impact of similar forces when amplified. Biomodel is not about prototype testing. In addition, it is important that the biomodelling in national security research should not be confused with or misunderstood for the mathematical models of biological and biomedical systems held in specialised repositories as part of medical and biological studies. They comprise vast selection of literature-based physiologically and pharmaceutically relevant mechanistic models in standard formats.

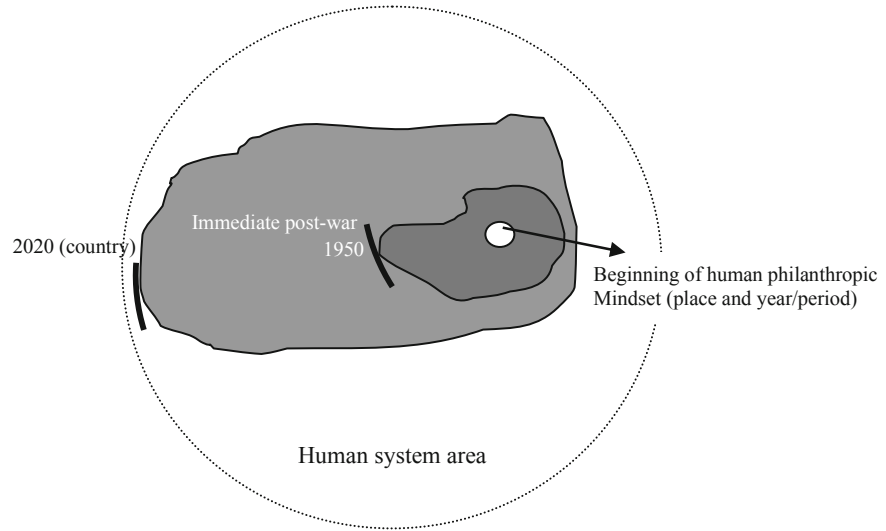

Biomodels in national security research are like test injections to understand allergic conditions before applying a real injection. It is the opinion of the author that history if correctly interpreted could be an excellent biomodel for national governance. But often history is vastly distorted, hence not advisable to follow without applicable corrections. History can misguide the biomodels based on it. History has many flaws and therefore not easy to interpret for national security interventions but for academic reasons. An identified biomodel could be used

cost-effectively in its natural habitats without having the need for a laboratory, especially by a government who has control over human habitats. It could be used very effectively. The principle behind it is observation of a scenario unfolding in a human system without intervening, but studying closely. This will not be easily understood without examples. The simplest of all the examples in biomodelling is a market survey—except for the fact that there is an element of inducement into it. It has certain artificiality when questionnaires or similar factors external to it are induced. Another example is the behavioural study of people around disputed borders in an inaccessible area for experiment. How to understand it? The situation can be introduced in a known and accessible system, which with suitable applications can be studied closely, say, for example, in a slum or a ghetto where life is equally under pressure. If the border people of a country are getting influenced by the next-door neighbour, the situation of what the neighbour does to them can be simulated within a chosen section of the slum or ghetto, where the attractions can be introduced from the urban side and watch their behaviour to appreciate the situation. Such biomodels already exist in the day-to-day life of every nation. One has to just watch the drama unfolding in real life to get the taste of biomodelling. Depending upon the result, counter measures can be tried out. Basically most of such things depend on behavioural changes to varying situations of select sample of human systems.

Often, a situation does not have to be created to understand the behaviour of people. The reaction of the residents of New York, USA, and also the behaviour of associated political, military and social systems to the terrorist attacks of 11 September 2001, if carefully studied, will give clear indications of how a superpower commune will react to such an incident in a larger context. In the biomodel that reflected the shock and awe on the face of every commuter to Washington, D.C., who stopped their cars on the highway and paused at the sight of the damaged Pentagon everyday in silence for months after the attack, the grit and determination of the majority of American people to get at the attackers with a thud were unmistakably apparent. In the symbol expressed by the national flag on every car that drove into the capital city was hidden the tacit affirmation of the people of America, the country, to their government that they didn't care for casualties in a war that they considered righteous. That broke the myth that the Americans were weary of body bags. Not all the time. However, such studies of instant biomodelling are never carried out seriously. Once done, it may point out to the fact that preparing the people to face such eventualities is as important as preventing the eventualities in national security strategy. Any location in any terrain relative to a specific incident can serve as a biomodel. Biomodelling is not about lessons learned. It is the study to understand how an appreciated system will unfold by watching a natural system made identical unfolds. The effort required is in making the natural system identical with the appreciated system and analysing the results. If studied properly, it is simulation in real life. It serves exactly as a simulation model in live form.

28.14 About Inkblot Model

The inkblot model (IBM)¹⁵ is not to be misconstrued with the psychological inkblot tests. It is not a test by itself. It is an identified model that could be used to explain a concept such as an evolution after hypothesis testing by a spread-out extension in a time-spatial system environment, where the variation is not uniform. The spread of a pandemic, war, shift of economic or political centres of gravity, sea level rise, and many such activities of national security matters can be expressed scientifically with acceptable accuracy by inkblot models by plotting the spread from available data. The inkblot can also be used to explain the spread of any evolutionary process such as the idea of corporate social responsibility (CSR) in a country or a business system. It has the characteristics of such a concept as it is scattered differentially within the global human system. A hypothetical example of the spread of an idea expressed as inkblot model (not to scale) is given in Fig. 28.6.¹⁶ The inkblot model, it is believed,

- Note:

¹⁶Adapted from Paleri, P. “The changing Concept of Corporate Philanthropy: Future Perspective.” In *Vision 2030: Creating sustainable growth accelerators in Management and IT*. Published by Principal, Chinmaya Institute of Technology, Kannur, December 15, 2017, pp. 1–13.

could be developed as a useful tool for simulation of evolution. This needs further research.

28.15 Models and Community

The community that deals with national security should understand the concept in its clear perspective. If not, there is a risk of deviation. Every citizen, being the member of a nation state, a formal group, is an active or passive player in national security. The degree of his or her contribution, positive or negative, has a bearing on NS_{max} . It is reiterated here that national security of a nation is different from the security of a nation. Community sampling for national security decisions, therefore, is important lest the decisions should fall outside the domain. Following is a sampling of community from the point of view of national security contribution.

- (a) Policy makers at all levels.
- (b) Researchers, scholars and students of strategy.
- (c) Enforcers and executors.
- (d) Information media personnel.
- (e) Support community: the common people.

The support community build up in national security participation is an important process that may get entangled with individual, political and administrative ambitions. But it is a process very vital to NS_{max} with heavy advantages. It is totally disorganised today all over the world with the majority community sectors mentioned above taking individual standpoints. Perhaps it may be known to many governmental organisations and the government itself that the common individual has an inherent urge to support the nation building process of the government. It is this urge that can be capitalised proactively and productively in community buildup. The gains are plenty. Such attempts are not made seriously anywhere in the world by any government. There is tremendous energy in such sectors that if unutilised proactively will not only be wasted, but also become destructive. Future may be different as the subject of national security revitalises in importance. Handling the community is a specialised subject and has to be done by the government and the national security organisations in a planned manner. This finding evolves from the principle that the population is the greatest strength of a country in maximising its national security.

28.16 Decision Making and Analysis

Decision making is the key process at every moment in time in any kind of individual and organised human endeavour. Decision making is into time. Effectiveness of decision making lies in its timing. The span of time from the

commencement to the end of the problem, whichever way its application turns out to be, is significant. Because, it is within this span of time the right moment for analysis, decision making and application hide. This moment is “the critical moment” of decision for action. The critical moment is vital because any decision taken before or after it may not meet with the right objective optimally, even if the decision is the best-chosen alternative. The effectiveness of a decision therefore lies on two parameters: 1) The best alternative to solve the problem (the decision), 2) The moment when it is most optimal to apply (the critical moment for application). Decisions taken in the individual and group capacity can be examined by those interested for their effectiveness with respect to the critical moment to understand this statement. It is not elaborated here. The time available for concluding a decision is the time from the identification of the problem to the critical moment of decision, and not the entire time span that may seemingly be available. Therefore, in decision making, the critical time span is what gives the decision analyst the time to test, experiment and change. Beyond the critical time, even a positive decision could become not only unavailing, but also counterproductive.

There are many tools available for professional decision making. They fall within the mathematical and non-mathematical realms. The tool that is normally used is based on its compatibility with the problem and familiarity of the decision maker with it. In national security decisions, one may have to use the theories of operations research and statistical analysis coupled with computer models extensively. Biomodelling could be an effective method for non-mathematical applications at macro level decisions, especially since those involved in national security decision making are not professional decision analysts, but political, bureaucratic, corporate, administrative and military executives besides individuals and leaders of various formal and informal groups in a society. Biomodelling is a find of the author and has not yet developed professionally, but surprisingly being used regularly without being aware of it in many decision making processes historically.

Decision making, according to psychologists, involves conscious and unconscious thinking process. Tools including models support this process. Humans rely on their intellect for thinking. The intellect uses tools like the computer and models including other brains in many such processes. Therefore, thinking becomes a multi-approach mode in which thinking style evolves—category thinking based on past experience and preoccupation, shared thinking through group active consensus thinking or accepted thinking and many by their widely intuitive thinking as they claim. Management by intuition¹⁷ is an accepted norm. Clausewitz in his famous treatise *On War* has mentioned about intuitive thinking as the quality of a commander as *coup d’oeil*.¹⁸ It is equally applicable to the chief executive officers and

¹⁷Paleri, P. “Management by Intuition.” *Annual brochure of the Indian Coast Guard*, eastern region, Chennai, 1991.

¹⁸Howard, M. and Paret, P. (eds.). (1984). *Carl Von Clausewitz On War*. Princeton University Press, 1984. p. 102. Carl Von Clausewitz speaks about *Coup d’oeil* as the intellect that even in the darkest hour retains some glimmerings of the inner light, which leads to truth. It is one of the qualities required in decision making to meet the challenges of uncertainty. *Coup d’oeil* deals with the “inner

heads of states. Edward de Bono, in his book, *Tactics*, mentions three routes to reaching a decision: the logical process, perceptual process and the intuitive process.¹⁹ According to him, logical thinking alone may not be enough for decision making. It is often substituted with perceptual and intuitive thinking. In perceptual thinking the uncertainties are formed as a map and examined carefully also using lateral (creative) thinking. Intuitive thinking is complex and is often based on past experience and consciousness of human nature. All these processes are involved in every decision process in varying degrees.

Decisions in national security matters are taken by people at the helm of affairs at various levels of hierarchy of governance in a nation state. These decisions are very consequential with respect to the objective of NS_{max} . The outcome of the decisions can be great success or totally disastrous with respect to the objective at the extremes. John Fitzgerald Kennedy (1917–1963)²⁰ in the middle of one of the crucial international events of the twentieth century, the Cuban Missile Crisis, had remarked, “*The essence of ultimate decision remains impenetrable to the observer—often indeed to the decider himself. . . . There will always be the dark and tangled stretches in the decision making process—mysterious even to those who may be most intimately involved*”.²¹

Decisions are made under various circumstances. Though all of them prevail upon uncertainty since decisions are for a consequential event of the future, the process can still be classified under trying situations that could be isolated from each other. In the management of decision making, the simplest of all is decision making under certainty. Here the only flaw that the decision-maker can make (and many are capable of it) is transmuting a certainty into an uncertainty. However, decision making under certainty is more an ideal baseline situation to explain the process since every problem has certain element of uncertainty within it. That naturally means decision making under uncertainty is the most common, and a variable situation because the uncertainty prevailing will keep changing as and when the process unfolds. Here is where the critical moment in time shows its optimality. The state of uncertainty at the critical moment is important in the decision paradigm, because beyond which the decision process cannot prolong without major reversals.

There are other decision situations too. Each has the uncertainty factor predominant in it. Decision making under competition, risk and conflict are three different situations that could be visualised. Every situation has its determinant factor for success or disaster guided by the human nature of aggressiveness with the underlying fear of insecurity. Every process of thinking is involved in each of these

eye” which certainly is applicable not only in war during the days of Clausewitz, but very much in the modern age when every activity of the humans undergoes scenarios similar to those of wars.

situations and the success comes by the more balanced and prepared process sometimes supported by chance. The comfortable model for decision making is breaking down the problem to the level under uncertainty in every situation and thereafter converting the uncertainty into certainty as far as possible within the critical moment in the time span and using the process of lateral and intuitive thinking to supplement the model.

28.17 Vitals of National Security

Vitals are the critical aspects of a thing, concept or system for its continuation. Primarily the term is used in explaining the conditions of human body. It means those that are critical for the sustainability of life. The whole concepts change when the vitals of national security are envisaged. While the vitals of human body will be known universally, it is not so with national security since the perception of the concept is not only different among human systems but also by time variations. This becomes further complicated if national security itself is seen as a vital for the nation. The vitals of national security will change based on how a government sees national security: the only vital for the nation or one of the vitals for the nation. Presently for the world national security is one of the vitals of the nation's survival, whereas this study advocates the concept as the only vital for the nation. In other words focusing on national security as envisaged in this study is just sufficient to evolve the national human system on a fast track towards the well-being of all. The former can be accepted if the governments consider the definition of national security as given in this study. The latter, as one of the vitals, is not having the consensus of this study. In this dilemma this examination is steered in a different direction to look at the vitals of national security from the point of view of decision decelerators: chance and chaos, the latter with a mix of entropy in the style of a cocktail and the enigmatic intuition. There is a quick run on them below.

28.17.1 *Chance*

Decisions are made for the future. The time that is yet to come is future in basic appreciation. It is riddled with various situations that will be controlled by uncertainty and risk as one envisages in the darkness of time yet coming. An interesting concept that lingers all around in future time is the element of chance (Chap. 4). Chance is all around. The part chance plays in human lives are never ever seriously studied and applied in national security governance. In fact, even in corporate management and governance, chance and its influence in decisions never figures or assessed seriously. Chance influences human life at all times. It percolates from every side. Studies on chance were on two fronts. One was to understand the causes

of chance to eliminate it totally.²² The interplay of chance in every element of national security will be visible, if the analyst sits close and prepares to face chance positively. Take the example of female foeticide. Can it be seen as an attempt to eliminate the cause of chance-induced, but unacceptable births in future? Here the effect itself is eliminated to kill the chance element. In more advanced cases babies may be designed genetically as per choice without leaving it to chance. In this case, chance stands for ignorance. Ignorance is eliminated to escape from the chance induced effect.

In the second front, the laws that govern chance events are studied. It gives a clear picture of the inner structure of chance. At the same time, the event may remain chancy. However, in scientific studies, the law of chances will support to eliminate the chancy event if negative. For example, the launch of a space shuttle could be governed by chance elements that may be destructive once it takes off. Risk-taking is strictly not managing chance, but playing with it ignorantly. Study of chance parameters and the laws that govern them may help to appreciate the occurrence of destructive events subsequent to a decision. The study of chance is with the well-perceived dictum that a chancy event always has a cause. Therefore, if the laws of chance can be mastered, the element of unpredictability can be minimised in an event. Chance is not causelessness. It is an event with a definite cause that is not known.²³ A chance event is the one in which the cause-effect chain is extremely complex and remains hidden from human perspective. The event, therefore, becomes unpredictable. Chance clutters human lives with uncertainty, despondency and anxiety. These situations bring major behavioural changes in a society. When it is said that the monsoon is unpredictable, the farmers' behaviour changes and prices of agricultural products fluctuate. Every element of national security is affected by chance. A flood can make a government not to go berserk with pandemonium but to hunt for opportunity to make money on the sly of sleaze.²⁴ It is, therefore, necessary the effects of chance in the elements are studied seriously. It is only possible by eliminating uncertainty in the chance element itself by understanding the causes, and prudent decision-making. Chance, by itself and as a medium of decision-making needs appropriate study in the concept of national security. The biggest question for research in chance is how to "create" a spot positive chance—chance that will yield quick positive result.

²³Ibid.

²⁴Sainath, P. (1996). *Everybody loves a good draught*. Penguin.

28.17.2 *Chaos-Entropy Mix*

Riding further into the realms of the unknown is a dream come true for anyone who “dares mighty things”.²⁵ The strategist in national security with the mind of an adventurer will not be able to resist such temptations. The areas open to such people are many—one of them is the strange theory of chaos. Chaos theory deals with order and disorder in systems. It applies to anything—from a broken glass to a vanished nation state. While the theory deals with the laws of physics, in its original shape it applies to human life in every sphere of activity.

The term chaos is used to explain certain instability situation.²⁶ An example is weather forecasting. Long-term weather predictions are notoriously unreliable under chaotic behaviour and not exactly by lack of knowledge of Newtonian laws as most people perceive and blame the meteorologists. Chaos ideally deals with unpredictability. It is also the concern of the humans about their lives. Is the ability of the humans in their uncanny knack of unpredictability by default, so that they do not steer into a fog at the macro level with respect to their terrains of existence or to have the final authority to press the button with the forces of nature itself? One doesn't know. And that long statement makes it a strange world. The theory of chaos thereby is closely related to decision-making and chance theory. An area that could be very well explored in national security studies. The non-linear, non-probability state (presumably) of chaos in the governance of a human system will be a researcher's paradise.

An interesting concept here, also used elsewhere in this book, is entropy. What does it mean? Students of thermal engineering will be familiar with the term connected with heat energy. According to one definition in thermal engineering related to heat engines, for an ideal engine, *the entropy is the measure of the unavailable energy when the sink temperature is kept constant* (where, hypothetically, the energy is not lost into heat). A casual reader in national security cannot appreciate this definition. Even for students of thermal engineering, it has to be explained with its associated system topics including equations. The concept of entropy may sound vague since it cannot be expressed with clarity can only be perceived with clarity! (This is an interesting aspect of human intellect—one can understand, but cannot express to convince). That is if one is serious about it and there is no reason why one has to be unless to learn and explain. Under imprecise descriptions and the prisoner's dilemma of sorts, entropy cannot be expressed as a clear-cut scientific quantity in social science. Therefore, seemingly there is an element of imprecision in its explanation.²⁷ Entropy is said to be irreversible, and

²⁵The huge parachute used by NASA's Perseverance rover to land on Mars contained a secret message, thanks to a puzzle lover on the spacecraft team. Systems engineer Ian Clark used a binary code to spell out “Dare Mighty Things” in the orange and white strips of the 70-foot (21-metre) parachute. The rover “Perseverance” also called “Percy” arrived Mars on 18 February 2021.

²⁶Penrose, R. (1989). *The emperor's new mind*. Oxford University Press. p.173.

²⁷Ibid. p. 309.

also said to increase in irreversible systems: aging, breaking of a window pane, a military coup, a government ordering an emergency, scrambling an egg—all are examples. It leads to a system change—a disorder of sorts, yes one can say. Unscrambling of the egg by rewinding or reverse motion is not possible. In such arguments, equally or more provocative concept appear from nowhere—time. Ever thought that time is nowhere but everywhere?

The term entropy may be best seen as energy that changes a system into something that it was not before and cannot be brought back by a reverse process. First the author would like to warn the reader that entropy is not disorder. Disorder is just disorder relative to the preceptor. But entropy is not relative that way; it is true and universal unless. . .well, can't say at this moment in time. It happens when the entropy in that system increases or one could also redefine the term that when a system changes under the conditions of irreversibility, there is an increase in "entropy" within the system.²⁸ This statement raises a question. In that case what changes the system? Is it time? Or is time again a concept that is perceptively visualised by an ever-changing system? Answers are clear to the physicists. But in governing national security, the government and the people have to be cautious about entropy and chance induced variables that may cut through. The research proposed is in this field—to know the influence of uncertainty or to be aware of it when decisions are made in national security matters.

28.17.3 *Intuition*

For a military historian and strategist, Clausewitz's *coup d'oeil* will come to memory while thinking about intuition. Military commanders, according to Clausewitz, depend heavily on intuitive thinking, especially, onscene during operations. The hunch about the immediate future is always there in every human. This hunch turns to a serious decision factor in everyone's life at one time or another. Leaders and executives in government make many decisions, even vital, based on intuition. National budgeting will have traces of intuitive assessments at the end. Intuitive process is a recognised process of decision making according to psychologists. In fact all the decisions will have traces of intuitions as an additional input. It is part of human intellect, the survival tool.

Research is required to gather information for decision making. Intuition is an added factor in research. But the need for clarity of information is the evidence most of the time. Intuitive findings cannot provide this clarity even if the decisions proved to be right. Hence intuitive analysis may not be acceptable in serious decision matters. The results of research needs sufficient proof apropos the methodology adopted. But there are ways of recognising intuitive research in national security.

²⁸ Author's own statement.

Will intuition replace careful analysis? An interesting find here are the ways people decide in a jiffy: toss a coin, touch a finger, take lot, pluck a love me -love me not petal. . . People have been practising many methods to make quick decisions. Do such acts awaken any kind of intuition centre inside the neural knots calling intuition? Well, frankly the author is not clear about the “thing”. This study therefore recommends depending on intuitive abilities alone may be with caution in serious matters.

There are scholars such as Daniel Kahneman who vouches on intuition having both advantages and disadvantages.²⁹ For him it is faster than a rational approach but more prone to error. But, for the author it is also rational. Intuition is perhaps one of the most frequently triggered human decision making processes from buying fish to stealing people’s money from government treasury. Intuitive thinking is not invoked, it walks in. Feel carefully the next time the gut feeling incites action. Clausewitz mentioned about *coup d’œil* by which the commander sees things through future as they unfold. Perhaps gut feeling is just a term for intuition. Intuition, being neural has to be part of the neural system spread out all over inside.

While linking intuition with research one may look at intuition as different from analytical thinking or similar to it. The latter seems to be more appropriate according to this study. It looks in the overall process of decision making that intuition is part of analytical thinking or rather inclusive of it. It is difficult to separate intuition from the analytical faculty of humans. It may require more serious studies by experts to separate the faculties at least in academic interest. Till then it is acceptable to consider every decision making process demands certain degree of intuitive ability in decision maker. It also means intuitive ability if a factor of decision making is vested in every human. Intuitive decisions need not be instantaneous as they seem to be. The speed an intuitive analysis acquires is because human intellect can discard unwanted information when decisions are made to avoid the clutter which is often the cause of delay and dirt in general thinking. Often the dirt is filtered away subsequently in analytical process by minimising the unwanted. Heuristic thinking which is mostly intuitive doesn’t suffer from this aspect. This statement however has a contradiction from the previous statement that intuitive thinking should not be seen separate from analytical thinking. Human thinking process uses every faculty of intellect with all its probable capacities in decision making. It also means there is nothing irrational in intuitive behaviour.

²⁹Laura Kutsch “Can We Rely on Our Intuition?” 15 August 2019. <https://www.scientificamerican.com/article/can-we-rely-on-our-intuition/>. Accessed 7 July 2020.

28.18 Summation

Governance is a professional activity. It is complex. It needs knowledge. Knowledge acquisition demands serious research that needs facilities for carrying them out. Any government that underestimates the value of research for decision making in governance will fail and end up as failed governments. Failed governments can break the continuum of nations unless they change the style prudently. It can also lead to micronisation and even total refreshing or reset of nations in other names. There are enough examples in the past. The law of invariance points out repeats. It will continue. Governments will have to watch out every moment.

Research in national security is the highest priority for any government. But no government gives research the priority it deserves. That is evident in the euphoria of a change in governments. This can be seen all over the globe. The euphoria of change in governments lasts short. That is the proof of governance by gut feeling and predetermined belief systems without any serious study. Research is time consuming. It is also expensive besides the need for professionally competitive researchers. Reluctance in research prior to decision making comes from the haste in getting things done. The governments are usually in a hurry and the time they have is limited. Hence they carry out selective appreciation of the situation and associated decision problems.

The main issues of research—time, money and competence—can be overcome by various means. Time is a major issue. Models and modelling can come handy to save time. Every research has its supportive models. Biomodels can be quite helpful. There are many historic biomodels. Though, most of them could be corrupted by distortion. They need to “hot washed” prior to using. Models could be mathematical or non-mathematical.

In mathematical modelling, quantitative techniques as operations research or otherwise are the preferred methods unless there are other choices. Operations research can also be applied to non-mathematical modelling. Mathematical analysis applies to a relatively small part of operations research studies. Whatever may be the techniques used, modelling studies require correct definition of the problem, collection of data, formulation of the type(s) of model(s) for studies, developing the model for deriving solutions, testing the model, preparing for ongoing application of the model, making decisions based on application, implementation and continuous observation for feedback and reassessment. The entire system is in a closed loop.

Research process in national security should identify novel ways to make it easier for governments to make quick and responsive decisions in short, medium and long-term frameworks. The boundaries of research need to cover the vitals too sometimes to the extremes covering chance, chaos-entropy mix and human intuitive ability. There are many questions. The research questions in national security are examined in the next chapter.

29.1 Introduction

The concept of national security covers everything about the survival of an individual human as part of a multitude of human systems by professional governance. The concept needs in-depth and continuous research as the human systems and associated techniques and styles of governance advance. What is conferred so far is an idea that the author expects could change the perception of the term presently in vogue all around. The idea could guide the governments to steer the passage in relative

smoothness to destination—the well-being of all. The idea is pragmatic though the world is neither uniform nor unified. It is not likely to happen even though the entire planet belongs to humans. The tendency of a life form including humans is to withdraw into a niche even if the ground is infinitesimally flat and free. It is visible in every living organism. Ever watched a living thing that collects its food and carries it to a closed corner to chew? That is the evidence for the corner or isolated space inclination for privacy in humans under the blatantly juxtaposing territorial instinct to invade and fortify. Funny these humans are. There are more. They can be perceived through many biomodels. All these show the world will never unite, unless. . .

At the same time the Planet is a vast global commons for humans to live and enjoy till the visa expires. This is the only fact that people do not know. In fact if one can watch carefully, the world belonged to all in the days when humans were in their primordial wardrobes. Since then they kept moving and settled where they felt better at the end of the journey. There was no feeling that the distant lands too belonged to them—the humans. This is a hypothesis that clash with human nature explained a brief moment ago. Perhaps demographic density may not be the reason why humans don't consider the whole planet belongs to them. So when they locate a place and migrate, it turns out to be the new world. That ain't true. Yes, this could be a research question. The travelling human limited themselves in demarcated niches on the hard surface of the planet, when the facilities found adequate and the pull from inside to go static. The pull for privacy and loneliness perhaps are inherent. If that is so the world may witness more micronisation. It is inevitable as if programmed in the intellect simultaneously with the push to invade and expand. Humans are confused. They are caught between the privacy of the cave and the openness of the expanse outside. The awareness about life and environment keeps growing and developing. It had taken different trends thereafter and will continue in a manner the humans feel more by instinct than by intuition or intelligence. This is an introduction as a hypothesis. Testing it may not cater much for the subject that is being dealt with—research questions in national security.

Since the time of dawning awareness, the objet d'art of intellect remained pickled in the brine of ever-mounting insecurity. Humans incarcerated themselves in caves and on trees fearing the unknown, which for them was everything they could sense. Even today they remain imprisoned in their caves called homes or trees called apartments, all within giant capsules called sovereign nations. They are still scared to the hilt. They haven't reached anywhere. Is it in the contract of life written in invisibly small types in the most ancient and human scripture of all, the DNA and its accompanier the RNA, the long and short of life? In spite of any limitations by origin, humans can still make life much better and "be in it" free and comfortable. This study believes.

Well-being in this sense is a kind of abstract format. To achieve it, there has to be a common script for acting out governance. In this study it is argued that abstraction is neither real nor unreal but a fact, an actuality of sorts, hence, acceptable as an existent. If so, an abstraction cannot be neglected and should be treated appropriately as a human attribute. It is under this lemma the concept of national security is

introduced here. It is also important to understand that this concept can apply not only to nations, the highest formal organisation of a human system, but also to any other formal groups as small as a family for individual and collective well-being by transfer of its principles. The concept of national security however cannot be applied to global security as the world is not a formal organisation but a collective in the absence of another accessible human niche elsewhere in the multiverse or at least in the universe where it is dotted in.

The entire statement so far could be totally wrong unless humans find answers to the questions that are yet to be asked seriously as the demand for answers are not authoritatively forthcoming. The examination of intensive research is aimed at strengthening the concept of national security and maximising it by national governance, in relation to the elements and terrains.

29.2 Questions in Research Process

Any research process needs to identify the research problem comprising research questions that lead to the answer the researcher sets out to answer. It is necessary for research in qualitative and quantitative terms. Choosing a research question is important for the researcher like filling the tank before a long drive. Research in national security is the mother of all researches. It is about humans. Any other research is part of it for a practitioner of national security.

Research in national security needs to dig for knowledge to apply in national governance. It is critical to overall and wholesome well-being. This criticality is the prime point in executive decisions. National governance is a bundle of executive decisions, all maddeningly critical to the purpose of governance. Compatibility is important because if a decision fails it can cause counterproductive results. Tradeoffs can play havoc for the governments in the thick of problems.

Research in national governance will not be an activity of mere data collection and analysis, deciding methodology and hypotheses testing. It will involve heavy modelling, intuitive analyses, feedback applications and various other factors that govern the unfolding of future in a country's life. The unfolding of future will put heavy demands over finding the past. The politicians, bureaucrats, and experts and professionals in government and related agencies are expected to be professionals in national security research. Decisions made by them prior to researching themselves may not be of much value. It will be visible in the results of governance.

This means research in national security is not an external activity similar to that being carried out by think tanks and funded organisations and individuals, but a user-executer concept. It cannot be partisan or selective. The research process should be familiar to all professionals in national security governance, starting with the head of governance of a country. Though it is an impossible concept, their decision making acuity at various levels should be research compatible directly or indirectly. There are many *prima facie* examples, though not quoted in this book to avoid prejudicial conclusions without firm testing. In simple terms, a decision maker should be able to

carry out research for information for decision making either directly or indirectly to his or her satisfaction. Even this is not possible at higher levels of governance as human systems are not attuned to prospecting the truth from facts. Besides this, another constraint is time. Time is a big spoiler too. Research should be adaptable to the time warp competitively.

National governance is what the national governments do. National governance is the activity process of national governments to establish the well-being of its people by optimising the elements of national security through integration of the terrains as applicable to that nation. National governance of a particular nation is not similar to another and cannot be considered inferior or subordinate to the type of governance in any other human system. Governance should not be based on assumptions. Research objectives should be guided by the need for eliminating assumptions in decision making.

The research objectives of national governance will vary. The elements, independently and in combination with respect to their interactivity, shall cover major part of research that will also include identification of new elements as and when they evolve. Each element has to be handled differently but jointly, and inclusively separated from the conditions of national security. Inclusive separation means calculating the tradeoffs in one with the impact of another as elements are mutually inclusive. The problem that a researcher can come across in this attempt is wrong diagnostics and mistaken priorities. The errors will make decisions ineffective. The associated danger of decision errors is that the results can turn ineffective and counterproductive. This can impact governments as well as the nation separately and as a whole.

Terrain specificity is another area. The primary terrain of national security is invariably the dry land with intermittent water catchments on which the humans are comfortable. There are other terrains beyond the realms of land; they developed slowly as humans advanced. There are physical and non-physical terrains and scope for more physical terrains beyond in the distant future. Research on terrains and terrain compatibility of national security elements in the existing and developing terrains will be a major area for research in national security.

Optimising the elements and integrating terrains and mutually aligning them with the process of governance are the primary aspect of research in national security governance. Therefore, the research questions should lead to this objective of research.

But all these depend upon the knowledge available to researchers on humans and human systems sans associated prejudices. Prejudices are obstacles to research. The research should get into the past and appropriate it to the future through the present. This effort should throw much light into the laws of invariance and limitations.

The leading questions that can come up in national security research are many. Most of the scholars are divided on issues related to human origin, evolutionary process and existence. The binary polarities of the human system heavily influence thinking and understanding what the human wants—the axes of power and belief system.

As an example, one can take a look at population, an interesting topic. Is population a boon or a bane for a nation's well-being? Answers will vary. In some quarters population is considered a contributor to national power. In some, increase in population means more poverty, starvation and decline in everything per capita. Words used to articulate such situations are population explosion, uncontrolled population growth and so on. There are belief systems that advocate increase in population; there are others who argue for serious reduction. Can both be right? Yes, it is possible if seen from relative perspectives. Governance can be streamlined accordingly. If population is a boon, it can be steered to higher productivity; if bane the outcome can be minimised to keep the well-being constant. It is like controlling the room temperature. If that is so, in such exchanged duality, any answer is acceptable provided it is correct. Otherwise one may cool the room when it is cold and heat it when the temperature is soaring. It's happening. Look around, one will see it in the world of governance. It can also be seen whether a government can choose one of them as a national policy. If not, it means both the arguments are wrong. The "how-to-think-what" process is a great support for research under such situations. The researched can put the questions by slicing them like a specimen in a biomedical lab or similar to salami cuts. May be the population answer is good for some and bad for some others. There are belief systems too based on population—one says more is good; other says less is fine. But they haven't realised most of the time nature makes strong statements on life creation and destruction. It is the forte of nature. That too with some purpose. Nature doesn't do research. It doesn't have to. But humans have to; they have limitations. It is selective with demand or nature. One doesn't know about the population problem, unless the answer is found through serious research. There is also another possibility based on the time and period. The population problem may be acceptable for some at a particular time for a particular period. If that is so, both the answers could be validated correctly.

There are systems where population is controlled by forced sterilisation of people. Such methods of governance are based on the belief that increase in population is a curse or not compatible with the governance policy. In some countries, the government encourages population growth by giving incentives to people who have more children. In some, population is increased under dictates thinking it will lead to supremacy of genre. Manoeuvred procreation may be to meet either the deficit in the population or ethnic count for gaining over the others. A question in demographic security governance is about the optimal count in population for a nation in national security. And if so, how to assess it? Will it be a bell curve? What should be the ethnic¹ count? Or how to wipe out the ethnic viewpoint totally and treat all humans under the unitary civilisation in the advancing worm tunnel? The fundamental questions on such issues can vary. If there is an optimum population will it vary with respect to the competence of the government to govern the people correctly investing them in national security management? In that case optimum population depends on the capability of governance. Here, governance changes fast, but people

¹See ethnic security for the meaning of ethnicity in this study (Chap. 20).

do not die off that quick. That means if particular governance can bring a higher-level optimum people, the next government by its inferior governance may find the optimum of the previous regime in excess to what they can handle. It is interesting to study the population parameter from conventional demographic studies. Such questions can make research in national security interesting.

No one would have ever examined it before—just like those who think increased population can be a problem to the well-being, one could also argue that a vast land area could be a problem for a nation in establishing its national security. Land is one of the terrains. Maintaining vigilance over a vast area is costly and the effect of it can be felt in border security, economic security, environmental security, etc. Is big always desirable? Is there an optimum limit to the land terrain? All these demands for identifying the NSI. Does this apply to the maritime terrain? What happens when a nation has a huge area in the ocean that it cannot look after? The Law of the Sea states that when a nation is not able to utilise its full capacity resources in the ocean terrain, it may share it with other nations that are geographically disadvantaged or landlocked.² What about land? There are many nations in the world with huge, but untouched land resources. How about them? How do geoproperty rights apply to a nation state? What about their extension to ocean property rights? How could the Law of the Sea, even though ratified in all respects differ from that over the land? Does the right to innocent passage encroach into sovereign rights? Is territorial sea just a moat around the castle or a kind of psychological security or concealed designs of the powerful? How are the rights over space to be adjusted for each nation in the world? Can a country share its uncultivated, but potentially arable land with another? If so, how? In the case of rising sea levels will the rules change? This way can nations claim variable maritime zones with respect to sea level rise which is certain? Is it legally or morally bound on a country to provide refuge and property rights to people displaced by sea-level rise without any consideration or can a country ask the displaced people of a country to transfer the rights over that country to the country of refuge even though gone under water? There are hosts of questions to make the research perennially interesting in human saga.

Can terrain vastness become a liability to a nation at any time in its existence? Or is there a situation where a nation should have more area in its terrain specificity? If so, which is that terrain (in both cases)? Is it sea or land (airspace is proportionate to its sea or land area and there will be corresponding changes when the situation on land or sea changes)? The question when refined could be, is there an optimum level of terrain specificity requirement for a nation over land and sea to balance its national security governance? Does the location of a nation, the geolocation, provide a geostrategic input, whether positive or negative, to a particular nation? If so, how to assess it? Were geolocations of nations a cause that pushed countries to wars and conflicts? Is the geographical location the main arbiter in increasing fundamentalism in many countries as we see it today? Did countries become “what they are” today by their geolocations on the Planet? If so, how will geolocations impact on the future of

²UNCLOS, Article 62.

national security governance? Will a country feel claustrophobic by constrained geolocation and breathe out geostrategically in territorial expansionism? Will a country fold itself into insularism and micro living just because it is scattered in pieces and isolated in a cluster? Terrain limitation and geographical location can certainly impact on national security governance. Will some countries be better off by limiting its territory? Can countries move out? (Don't rubbish this question too soon). By the way who ultimately owns a country? Is there anyone? The political connotations of these statements are quite chary, but the world is changing continuously and the people are poised to become more and more responsive in future. Many of the fixations of the day can become redundant in future. They can also be replaced by new ones that one could watch out now. Ideas that are not sold today may find in demand tomorrow. Is this right? Well, check it.

There are studies on the subject in similar lines. An example is the requirement of arable land and the spread of forests. There are also studies on resource requirement. But the approach to all these studies will change under the arguments on optimising land and population. This does not mean that the excess land has to be detached or shortage made good by annexation; also good governance does not advocate luring the "unwanted" population to exotic gas chambers after shaving their hair for export to convert into wigs for hairless craniums. The studies may pave the way for understanding the constraints and taking care of it.

There are many more such questions that can be framed every moment of national security governance for articulated and inquisitive thinking. The subsections below examine some of these factors more or less sequentially.

29.3 Research Factors

Identifying the factors of research in national security will support framing research questions on the subject, as the way it is conceptualised. The factors can be decided as appreciated by research. They shall keep varying with respect to the research questions. A general set of factors are identified below. They are briefly examined thereafter. There could be more factors which individual researchers can identify.

1. Human system specificity.
2. Concept of national security.
3. Threat perception and analysis.
4. Elements of national security.
5. Conditions of national security.
6. Terrain specificity.
7. External rudiments.
8. Governance.
9. Modelling national security.
10. Assessing national security.
11. Indexing national security.

12. Auditing national security governance.
13. Futuristic impact assessments.
14. Global systems.

Each of these factors is examined below with selected questions for research. This can be further expanded according to the researchers' choice.

29.3.1 Human System Specificity (Factor #1)

Human system specificity involves the “past” and an evolutionary trip down the lane to arrive at the modern human for the new century (twenty-first) and a declaration of *Homo sapiens* from now on as sapien humans (in strategic studies and governance). This is the intent of the author that can be changed based on the views of the people. This book advocates such an appreciation, suggested basically to improve the self-esteem, not the biological specificity, of the present and future human system that may lead, if governments are mutually concerned and conscientious, towards many resolutions starting with Millennium Development Goals (MDG) (2005) through the Sustainable Development Goals (SDG) widely known as Agenda 2030. The year to begin the century of Sapien humans or sapiens is 2021 with the call for ceasefire in Syrian War (5 March 2020) and subsequently closing the breach in the Nagorno-Karabakh ceasefire (9 November 2020) on 13 November 2020. Conflicts and killings under “subhuman intelligence”³ which only *Homo sapiens* are capable of should end without waiting for natural genetic refreshers and makeovers. That will take a long time. It is time to advance in thinking and turn to sapiens, more advanced in intellectual usage. That may also expedite genetics renovation for the better. Yes, mind impacts the tiny gems called the genes. Love them. Make them believe humans are better than what they are. That may turn out to be fast track gene transformation for the better. No, don't be sceptical. Please take it seriously.

Human system specificity needs to be explored and examined to understand the origin of life forms on Earth and how they evolved to the present-day sapien and human systems. The available historiography has problems with truth, facts and aberrations. The information need to be repeatedly hot washed before applying to GBNS as accepted. This is natural in such fields especially considering the limitations of human systems. The sapien for this study is the honorific title given to the present-day humans basically to elevate them beyond the great apes and subsequent homo bipeds for upgradation that will support the need for a study of this sort aimed at human well-being in a different level. At the same time the term human system is retained instead of sapien system as it may interfere with other studies on behavioural science, political science, etc. Another reason is that the definition of sapiens is not yet given and hence is a question in this section.

³ Author's term.

Many interesting questions can originate from this factor. Below are for samples.

29.3.1.1 How was Life Formed Originally on Earth?

This question can also be put in a different way: is the original source of life external or internal? There are arguments that life was transplanted from deep space into the planet like planting a sapling purchased from a nearby nursery in one's new home. Have a closer look. Nothing impossible or difficult has happened in nature so far.

There are many supporting factors, intuitive or otherwise, for making research questions in this statement. Some are:

- Scientific appreciations of scholars on the subject.⁴
- Unequal distribution of humans by origin over the planet.
- Unequal distribution of metals and minerals over the planet.
- The present behaviour of life distribution in⁵ and on the planet's crest shows signs of transplant.

29.3.1.2 When and Where was the First Human (Homo sapien) Born?

This may not seem to be a critical question in national security governance. The humans have been surviving for long in spite of interruptions locally and globally. Even Ice Ages did not interrupt or delete humans a la little dinos. They came through even ice ages.⁶ There seems to be competition between animated and unanimated forms of nature. Life seems to be more powerful if seen separately. But it doesn't seem so. Life is virtually part of nature along with unanimated matter. Everything is matter that ultimately gets swallowed by energy. That is physics, the only science and the ultimate truth as humans know (author). If that is true, physics force-designs everything, even writing this book. The answer to this question will help to establish the continuum factor of humans that will assist in understanding many related questions in decision making in governance.

Humans are used to life. Majority of humans do not want to know who came first. They know there was somebody before them. That knowledge is sufficient even to

⁴Chotiner, I. "What if life did not originate on Earth?" <https://www.newyorker.com/news/q-and-a/what-if-life-did-not-originate-on-earth>. Accessed 22 January 2020.

⁵Luana Steffen. (8 May 2020). "Life is found deep in Earth's crust under the sea". <https://www.intelligentliving.co/life-deep-earths-crust-under-sea/>, Accessed 29 August 2020. Scientific researchers have discovered living microorganisms deep in Earth's lower crust rocks. The location they consider as the last frontier of the exploration for life on Earth. But one can't say.

raid or storm the Capitol surrounded by exotic Magnolias⁷ around or White House (*Bely Dom*⁸) on the embankment. It had happened in recent history. It is sad It is not the desired sapien behaviour for tomorrow.

Better comprehension is required to govern demographically and somatopsychically⁹ advancing humans. Yes, human design has to advance with time making it more complicated to govern by old and ancient methods which is prevailing all over. Clarity is required to understand the differences between the inliers and the outliers and their hybrid progenies of the day. In other words, the anatomical and physiological centrum of population birth and growth hold vital clues in understanding and modifying patterns of governance. The dynamic human migrates and the other stays put. Why? The answer may lead to some decision factors, in migratory characteristics, human system formation, genetic appreciation in the genomic terrain and the need to look at humans as members of a unitary civilisation. There are more. The first humans were believed to have appeared at different times in different places. The first human ancestors, apelike creatures walking habitually on two legs, appeared in Africa between five million and seven million years ago. But continued research shows Africa was not the only domain. Traces are found in China, India and others. But the interesting fact is that the land masses that carry these points of origin of birth today were not where they were today. Their global addresses, the coordinates, have changed.

29.3.1.3 When did Humans Become Humans?

This question may sound silly. It doesn't matter as long as it catches attention. *Homo sapiens* were attempting crude stone tools around 2.5 million years ago. But people who look like humans evolved by at least 130,000 years ago from ancestors who had remained in Africa. That is when, the scientists feel, their brains reached today's size. Is that the right criteria or is it the ability to use intellect. Intellect is distributed in the whole neural network. The cranium holds only the main centre, the brain. The brawn carries the huge network of system intellect. Some say there are about 60 km of nervous or neuronics lines inside the human brain and the brawn combined. One could appreciate it as part of the amazing self. That is fine. So, it will help if one knows when all these happened and the new biped claimed to have separated from the great apes completely.

⁷The author considers magnolias the most exotic flower in the Planet. (One of the reasons could be that he has not seen many others).

⁸The Russian White House.

⁹Paleri, P. (2018). *Human investment management: raise the level by capitalising human*. Springer Nature Singapore Pte Ltd. p. 191.

29.3.1.4 Are Humans an Exclusive Species?

If the separation from great apes is a claim, then humans who are humans will have to be seen as an exclusive species from all other attached and allied great apes, hominids and so on, though evolution is a continuum, for the purpose of governance. This date could be taken as the date to understand the spread of humans around the Planet by biological gradients of survival and settlements for calculations in national security governance.

29.3.1.5 Is it Appropriate to Call the Present-Day Humans as Sapiens?

It calls for a definition for sapien scientifically and also relevant to this study. Sapien is not a standalone scientific term. It could become one. It is a term coined by the author for this study with a purpose. The term has been used by a scholarly author appropriately as the title to illuminate the history of *Homo sapiens-sapiens*.¹⁰ This book considers the term sapiens appropriate for humans to project them as more advanced intellectually from the *Homo sapiens* of the past from this time¹¹ onwards. This is a more advanced term that the author prefers to bring in vogue even if they are still rattled in the imprecision of the behaviours conditioned by the past. The purpose is to separate humans from all others in the past and minimise the distortion in history and the world human family to turn into a more positive direction as a sublime suggestion though not scientifically, but psychologically. If so this is the appropriate time. Yes, there is a drawback. This approach may make the humans in the past look worse than the present. The author feels that they shouldn't have any objection and according to evolution the one younger to the author is any way should be of better design being more advanced in the evolutionary scale. And, evolution is neither unreal nor an abstraction.

29.3.2 Concept of National Security (Factor #2)

The questions for research cover the overall concept of national security in the new format as mentioned in this study. The idea is to examine the feasibility of the new theory for research and governance under this factor. The idea of national security, identifying the metrics, assessing the level of national security through the metrics, indexing national security, etc. can be included in it. This depends upon international

¹⁰Harari, Y. N. (2015). *Sapiens: a brief history of humankind*. Penguin Random House.

¹¹The exact date chosen is 5 March 2020 when the Syrian War came to a cease fire with the hope the "wars are over..." according to the author. Sapien behaviour is a kind of dictum for the *Homo sapiens* of the day for a better life and for governments to decide on well being as the final objective in GBNS. Period.

consensus, standardised methodology, application factor for each nation based on the exclusive parameters to arrive at a common scale, etc.

The concept of national security according to the study is about satisfying the needs and wants of humans, explained as apparent security and perceived security by directly governing the former and indirectly linking the latter by the government whatever type it may be for the well-being of the people within the specific human system which is the largest of all formal human system standing exclusively as a geostrategic entity. Many questions originate from the concept from its preamble and definitions itself.

29.3.2.1 What is Human Well-Being?

Presently, in this study, well-being is considered to be the sentient feeling of sanguinity sans anxiety a human generates and carries forward within at any given time. The feeling may not induce hormonal happiness in a person but will prevent or pre-empt any personal anxiety and mitigate the existing anxiety by self-appreciation and evaluation providing hope for the future.

29.3.2.2 What All Factors Contribute to Human well-being?

While in search of the idea of well-being, the researchers may come across different terminologies like happiness, comfort, development, technology providers, etc., that have serious bearing towards their perception of national security. These are to be examined and separated from the main topic of well-being to avoid misconstrued judgments. By doing so, the research will lead to associated fields of human concern.

29.3.2.3 How Should Governments Handle Perceived Security—The Mental Factor in National Security?

The problem in this context is the interplay of perceived security with apparent security. The government can only provide apparent security. But, without perceived.

29.3.2.4 What Are the Metrics for Measuring National Security?

Measuring national security means identification of metrics. National security index is the compounded form of measurable units for which exceptional and accurate assessment procedures are required. It means quantifying optimisation of elements and integration of terrains with governance and random examination of the feeling of well-being in people. The metrics will not be accurate, but can be assessed by creating a global standard as the index is basically for measuring the effectiveness

of governing measures, quantifying efficiency of governance and comparing the quality of life of the people within the country for an overall average by random and continuous surveys.

29.3.2.5 What Are the Factors That Will Go in the Calculation of NSI?

The formula for such assessment should be universal without bias conducted by agencies that are unprejudiced. Though it will be difficult to arrive at accurately, a relatively competent way of assessing the well-being and the overall national security index (NSI) for a specific period of time can be realistically arrived at. NSI is the outcome of national security assessment. It provides for the assessment of governance and comparative analysis. Any process of indexing should be possible in governance and development associated with that. If so, the parameters for indexing national security become the key factors for identification by research in this case. The process of measurement of these parameters will be another area. These processes need to be standardised at institutional, national or international level.

29.3.2.6 Is NSI a Better Method of Indexing the Human System Well-Being?

Introduction of the idea of NSI will bring serious changes in governance. Public attention will become more focused on the subject because of clarity. The public equipped with correct information will be able to place their demands on the government and also analyse the issues of governance. People participation in governance will be more associative than critical. Generally, the opinion of the people sways under the propaganda and grapevine. People also lack clarity of information and ability to interpret and analyse the inputs. This makes the belief systems to control response from the public. Under such changes, there are possibilities for measures of governance to transform for the better. The probable changes in governance subsequent to introduction of NSI can be identified by research. Introduction of NSI, after a serious research and examination for validation and acceptance is expected to give the much-needed fillip to national security governance.

29.3.2.7 What Are the Changes Expected to Take Place in the Evolution of the Concept of National Security in the Immediate Future That Will Need the Attention of the Governments?

Law of invariance is not about change that will not happen but humans will not be able to perceive the way it is occurring while it is happening. There will be change in the concept of national security too. This topic comes under the futuristic

appreciation of national security. But for the present, it is about the immediate future that the governments and national security practitioners have to practice it as agents of change. Therefore, the changes in the immediate future or relatively short term need to be appreciated. Since the original findings of the author in the 1990s during the studies, there have been many changes in the concept in its elements and terrains.

29.3.2.8 Does the Term Spiritual Security Need a Makeover as the Concept of Spirituality Can be Mistaken for Spiritual Security?

In this study, spiritual security is the term given to all those a human wants beyond apparent security where the basic needs are met through governance. Spiritual security is beyond the provisions of the government except to the cases where governments should not interfere unless it clashes with the constitutional law and rule of law that impacts on others whose belief systems are not compatible. It is not necessary for the government to modify it. But changing the term is not recommended as spirituality is one of the forms of spiritual security related to religious belief systems.

29.3.3 Threat Perception and Analysis (Factor #3)

This factor examines the threat matrix cube with respect to the problem to decide action and finding ways to deal with it if so decided in any of the three formats—preventive, pre-emptive or mitigative. Perceiving and analysing threat to a target is important to prevent or pre-empt the loss of target or mitigate the damages if the threat hits the target. This is how every human action is governed in a conflict decision system in a situation.

29.3.3.1 Is the Threat Matrix Cube a Practical Model for Analysis?

Predicting threat perception under the threat matrix cube and intercepting threat to various elements of national security by pre-emption or in the post active stage in the fly box model will be an independent and extensive area of study.

29.3.3.2 What Are the Requirements for a Threat to Become a threat?

One of the requirements for a threat to become a threat is that it should recognise a target that is threat attractive.

29.3.3.3 Can a Threat be Turned to the Benefit of Governance?

In a mention on SWOT analysis elsewhere in the book, the author commented on turning weaknesses into strength and threat to opportunities (Chap. 4). Under this argument the author believes threats in national security can be turned to opportunistic advantages in governance. There are examples in history of such turns around. That is also a way of managing threat. But this needs to be researched or each situation in the flybox or any other model in governance.

29.3.3.4 What Are the Factors of Threat Intensity?

In the threat to target equation the intensity of threat varies as long as it exists. The intensity can increase or decrease on the passage to encounter with the target. Calibrating and managing the intensity of threat needs to be studied with respect to decision on prevention, pre-emption and consenting encounter.

29.3.3.5 Is the Value of a Target Based on the Threat it Attracts?

Threat and target are symbiotic. There can't be a target unless there is a threat to it. A target is not a vital governing element unless it is within a threat matrix. This lemma is important in handling a threat-to-target situation.

29.3.4 Elements of National Security (Factor #4)

All the 16 elements of national security are included in this besides examining the possibility of new elements coming in future. Their interactiveness and tradeoffs and relations with terrains are also needed to be researched. An element of national security is considered to be a single paramount entity related to human well-being with an independent profile as a contributor to its maximisation having strong compatibility with other identified elements in mutual interaction. In this case, the characteristics of an element that makes it distinct from other aspects of national security, such as conditions, threats, weapons, technology, education, etc., could still be researched for clarity so that non-elements are not treated as elements in national security management. This differentiation, between elements and non-elements, is vital in the application of national security principles.

Every aspect of an identified element of national security needs thorough investigation by research to understand them better in their evolution and status with respect to time. This will also include studying its transformation by evolution and the time when it is likely to cease to be an element in future. There are also chances that an element may cease to be an element, split into more elements or merge with

an existing element in future. The probability of such changes could be verified through research.

Each element will have its centre of gravity; that is the point where it cannot afford to take a hit. Does the centre of gravity of an element of national security change with respect to each nation as well as with respect to time and situation for a nation? The question applies to the collective centre of gravity of the elements also. Next is will there be a principal element at any particular time for a nation that needs maximum attention? If so, how is it identified? All these bring together the importance of national security assessment on a minute-to-minute evaluation process. There is no other subject in a nation's governance that calls for 24×365 h a year scrutiny and preparedness. How many governments are aware of it? Banks, stock exchanges, war rooms and even computers can blink a second or much more, but the national security centre has to remove the eyelids permanently and develop the fish eye view. That is, if the governments are serious about it.

The elements are interconnected. They are not mutually exclusive. The interaction of elements and the effect of an incremental change in one on the other or a combination of elements is a matter of serious study. It is the net impact that will ultimately reflect in NS_{\max} . The study may lead in identifying the corresponding interactive coefficients between elements.

The elements of national security are those that are integral to national security governance in which one influences the other under mutual inclusiveness. Governments need to align them and optimise for maximising national security. The research questions in each of the elements will depend upon various factors associated with each and those in aligning them for optimisation. The governments will have to see them apropos their requirements and situations that will vary. In general, the research questions may involve those related to the interactiveness, continuity, redundancy, appearance of new elements, etc. Questions on each of the element will be country specific and based on the type and style of governance and may change with the governments.

29.3.5 Conditions of National Security (Factor #5)

There can be conflicting opinions about various aspects considered as elements of national security. These include rule of law, internal security, happiness, terrorism, religious fundamentalism, political fundamentalism, mind control and so on. Such factors will require periodic examination to appreciate their exactness with the concept of national security. The influencing factors of national security—conditional situations that involve threats will need serious study to visualise them from the correct perspective and not as elements of national security to avoid wrong diagnostics and identify adequate countermeasures. Such conditional situations and threats will include:

- *Terrorism and Militant Activism.* The terminology of terrorism and militant activism is incorrect from semantics as well as conceptualisation point of view, because terrorism today is part of militant activism and not a separate activity. At the same time, terrorism was not something where militancy alone was involved in the past and it is one of the early concepts that could be traced much beyond the well-known times in history. Terrorism is a threat and it has to be seen that way. Handling terrorism and militant activism need considerable amount of research and periodic review since the scenario changes in this fast-developing anti-force of yore.
- *Insurgency.* Insurgency is another point that may also be attributable to terror tactics. Counter-insurgency is a word used in strategic security applications. But the effectiveness is very limited. One of the reasons may be that the cause is more important than the effect itself. Actual solution may lie in eliminating the cause and not mitigating the effect.
- *Corruption and Sleaze.* Corruption is a behaviour pattern originated from fear and insecurity. It is worldwide and very original from the historic world. Corruption is an anti-force and thereby a roadblock in handling national security. It is used excessively for easy access into the system. Corruption is an access route for the determined. The study of corruption for prevention and elimination from the system of governance may give a fillip to national security efforts.
- *Trafficking (Crimes 3+).*
- *Narcotics.* Narco-traffic is the primary route for financing terrorism and violence among others. The United States declared “war on drugs” in the 1980s. It has been heightened to an issue of national security and the government was debating to involve the military. Finally, the government succumbed to its own pressure and military actions were initiated against the drug cartels in Colombia. Those days the global drug trafficking was at about US\$500billion. The trafficking only increased proving it to the world that military action is not the effective method of controlling drug trafficking. While drug traffic is on a burner, the United States has lighted up another on “war on terror” early in the new century. There are similarities. Again it is military action. Will this too meet the fate of containing drug trafficking? It will be a time bound problem to solve unless examined at least in a biomodel. Both the subjects are serious for the world to react. The process is what is to be seen by research.
- *Arms Trafficking.* The finances in arms trafficking float from drug money, which in turn supports terrorism and armed insurgencies. This is what the law enforcement agencies believe. Arms trafficking is perhaps one of the highest paying businesses in the world. It is a world of its own with internecine complications. Arms trafficking cover all types of arms: from weapons of mass destruction (WMD) to small arms. Everything is in demand. The demand for arms perhaps is only outweighed by the demand for water and air in the world. Small arms, otherwise called light weapons, have been central to any conflict. The demand is from individuals to groups. Demand increases because arms generate the much-needed asymmetry in combat and conflict situations. Arms trafficking is a threat that could cover the entire matrix of the threat matrix cube and an area under

constant vigil by all, including strategists, but arms control regimes are unable to cope the way the world splurges and enjoys the orgies of the market.

- *Organ trafficking.* Organ trafficking is a heinous crime that is picking up fast around the world. It is included as additional in the terminology of Crims3 in this study.
- *Other Transnational Crimes.* Transnational crimes are those that are not contained within nation states and have influence over global crimes. Terrorism, and drugs and arms trafficking have already been explained. In addition, there are varieties of transnational crimes like illicit human trafficking and white collar-crimes of the world that crosses boundaries of nation states over the land, air and oceans. All these crimes come under scrutiny in national security evaluation. These subjects will be of great interest in analysis and research.
- *Politicking.* Politics is a dirty word for some. But politicking could be worse as a block in the arteries of not only governance, but also to the objective of NS_{max} itself. It may not be so in an informed and empowered democracy. Preparing the people including politicians for effective politicking in governance with people participation in the correct direction is a recommended subject of study.
- *WMD—Influence and Proliferation.* There is a mention of WMD in arms trafficking. But, WMDs have been high profile topics worldwide. It is widely discussed in disarmament dialogues. WMDs are nothing but weapons to start with and the fear is the possession and use of them, especially by aspiring players who may like to topple regimes destructively. The psychology of fear of WMDs may be equally interesting to the urge to possess them. It will make a serious subject of study because WMDs may mean different to different countries.
- *Power States Involvement in the Internal Affairs of Others.* Power projection by the powerful nations will be a matter of concern to many nations. The issue here is the quantum of concern that a nation has to go through. Overly concern may perhaps is not necessary because it may affect the main objective of national security. The impact of the acts of superstate in a particular nation's national security objectives should be limited to the actual effect rather than perceived effect. Arriving at the actual effect and the ways out of it, if it is adverse, are the topics of research in handling the superstate and living with it in a (un)certain world.
- Other areas that are not threats, but can influence national security are to be seen from their correct perspective. There will be questions such as:
- Does education supplement national security efforts? If so, how? Ideally, education means knowledge accumulation. But it could also mean accumulation of distorted information and thereby knowledge corruption. It is the case in most of the education systems. Religion and history perhaps are the most distorted topics in the education system whether private or government sponsored. The core issue here is providing correct information to those who have the right to information—that means to every citizen of a country.
- What is the influence of religious beliefs and cult behaviour in national security efforts? According to the findings of this book, religion is considered an essential element of spiritual security that keeps the human societies in balance, but outside

the purview of national security studies. But its complementary functions will be of great interest in the studies.

29.3.6 Terrain Specificity (Factor #6)

This includes all matters related to the terrains identified in this study, terrains that may evolve in future, change of terrains and so on. Eight terrains have been identified—land, ocean, sky, contiguous space, deep space, cyber space, genome (genomic space) and biome (human microbiomic space). The ever paranoid world may still play around with various other terrains such as mindscape¹² as it happened during the Cold War and still going on with many deviations from the past. The questions that may come in terrain specificity may include the following:

- Integrating terrains with themselves.
- Integrating terrains with national security elements.
- Protecting the terrains in the national interest.
- Merging terrains in future.
- Identifying new terrains.
- Rule of law associated with the terrains. For example, is it possible to have a UN Convention on the Law of Space (UNCLOS) similar to UNCLOS III, 1982 meant for the ocean terrain?

29.3.7 External Rudiments (Factor #7)

The external rudiments are those associated with national security that comes up for consideration on elements, terrains and their interplay periodically. There are various such externals that could be identified for research. They include the much-used terms in governance such as well-being, chance, entropy, chaos, anteforce and so on. They need to be refreshed through research periodically.

¹²This could be an absurd and totally wrong prediction because what is in store for the future is unpredictable in a world that is driven by chance—the causes that are not known. Genetic and other technologies can alter personalities according to Tom Butler-Bowdon the author of the book, *50 Self-Help Classics* (London: Nicholas Brealy Publishing), 2003, p. 8. According to the author, scarier is the possibility that the humans may be able to keep the memories alive by transferring them to new corpus long after the body has given up just like a computer drive transferring data. Well, in that case the mindscape certainly ought to become another terrain.

29.3.8 National Governance (Factor #8)

The exact nature and definition of government and governance is yet to be defined for unified acceptance. There are many definitions and practices in vogue. The variations in definitions lead to this conclusion. What exactly is governance and what is its relation with governments and political systems? It is a stagnant field based on old theories of the past in new convictions of the present. However, national security research neither enters nor challenges the field of established political and other social sciences that deals with human system. It only deals with national governance towards human well-being. Governance is the action whereas government is their agent who does it for them. The clarity ends there abruptly.

The form and types of governance is another issue to settle. The cracker box is opened in this study. It can catch fire. For everybody, except the author, democracy is the most modern type of governmental system though it began aeons back. For many it is the best. But it is not the choice of all as a type of governmental system. There are various other types of governments with which many of them are comfortable. This creates confusion about democracy as a type of government. It is too old and perhaps older than many other types that came after it. Every form of government including the most dangerous or despised, whichever it is, still have peoples participation by acceptance, involvement, non-acceptance, coercive submission, indifference or in any other format. If that is so all forms of government are either democratic through an agent called government or anarchic that is direct. This study sticks to that argument singularly. This was explained earlier. This argument needs extensive study and research to decide upon forms and types of governance and governments to separate the grain from the chaff. The only difference in this study (that may cause further confusion, though) is that the type of government is not critical for national security maximisation as long as the form is democratic and not anarchic. Because, the national security analysis needs the “agent” of governance to roast. Anarchy is direct. Whether it is democracy or anarchy or any other form the scholars want to establish this study deals with governance and not governments. But this could lead the rest of the social sciences to rethink their ideas.

29.3.9 Modelling National Security (Factor #9)

Modelling national security studies is a firm topic for research. The modelling methods available are mathematical and non-mathematical research laboratory models and biomodelling under live situations and inkblot modelling under evolutionary research. Extensive research is required in these areas.

29.3.10 Assessing National Security (Factor #10)

This involves the metrics, measurements and procedures for establishing the national security index.

29.3.11 Indexing National Security (Factor #11)

This is the crux of the research in national security studies. This involves indexing national security from the results obtained through measures recommended in the research process of assessing national security and validating them for universal acceptance as an index for comparative analysis of human systems of identified geopolitical entities.

29.3.12 Auditing National Security Governance (Factor #12)

There will be a requirement to audit national security. The methods of audit are internal as well as external to the government for the purpose of governance. Audits external to the state by recognised international bodies for establishing the NSI of the state will be another requirement. Auditing governance by national security (GBNS) or otherwise national security governance will be a new field if the concept is introduced in governance. This needs to be examined by research.

29.3.13 Futuristic Impact Assessments (Factor #13)

Changes are anticipated in the concept of national security in course of time. The core definition, however, will remain unchanged. Impact of these changes on the concept itself will be important. Therefore, the study of the concept with respect to changes and predicting those changes become another area of significance. This means the study on the evolution of the concept and its extension into future should be constantly researched and reviewed.

29.3.14 Global Systems (Factor #14)

The interplay of spiritual security with national security as a continuum will provide much scope for research though will face serious criticisms from established sources. Dual polarity under conditioned binary axes of power as political and faith systems

of human system is a new focus in this study. This will require extensive research to establish facts and plan further development. The research questions may fall under interactive aspects of national security with respect to a particular nation and its involvement in global affairs.

Global security is the ultimate concept into which the concept of national security will gravitate. It is not a tested statement but a hypothesis that has indicators. The UN itself is an indicator of the shift towards global security, whereas the concept of the superstate and its existential problems cause the counterforce (here the word anti-force is not used since it is the counterforce against governance of national security, though in concept both are similar) to act against the process. In this hold, which way the world will swing will be an interesting study.

The concept of a world body and its value for the emerging world need to be studied. Are there chances for the UN to slip into a vegetative state or go the League of Nations way? The secretaries general have been at the helm of affairs in the UN to keep it afloat and make way through the ocean of nations sincerely. They have been succeeding. In this melee the future of UN and its value are topics of study. The idea of global security outside the shadow of the UN needs to be examined to assess the capacity of the collective agency to hold the global system. If so it needs to be seen whether UN could be the caring agent for national security, especially when the powers of national governments vacillate in the developing knowledge world. There are many such questions on global systems that demand serious research.

29.4 Government and Governance

A perfect system of government and methodology of governance for all seasons is yet to be devised as can be seen from various arguments on such issues. Issues of government and governance may seem widely complex depending upon the angle of perception. It is very much understandable that there is no outright panacea for issues of governance. All the more, there is no end to human capabilities to device new and modern methodologies and systems for advancement. This could work out ambitiously in national security governance also. The areas that involve studies in this topic could be vast and will pose many questions.

Who governs national security? Is it the government? Will it change? This book identifies the “king”, the government, the agent, as the national security provider. The people may accept “the king” or the type equivalent as the agent to govern them. The constitution where exists or any other laws and principles accepted or followed by the people provide the authority to the people to govern their state of affairs the way they decide, accept or submit. This authority is delegated to the agent. Here is where the catch lies. The constitutions need not say how they should be governed; hence the saying that the people get the government they deserve. From the objective of national security, there is only one way to govern: maximising national security. The practicality of such a statement needs to be evaluated seriously and reviewed periodically.

If the government is the provider of national security, how it should govern? The answer to this question depends on the constitution and the will and expertise of the government. It needs to be tested for practicality. All the governments are of the people whether they agree fully or partially or totally disagree by acceptance or non-acceptance. People are party to governance and thereby stakeholders. The system of people's participation in governance (through their representatives and public information rights) has been ancient and has many historic biomodels. Is the system practiced today in the so-called people's rule similar to those in the past? Are the current forms and types an act of balancing against opposite views? Is there a way people can participate beyond the capacity of their agents? Do the people really care about the government in meeting their individual needs? There are many such questions.

People's willing and inclusive participation in national security shift the idea few notches above the repent format. What are the chances of new forms of governmental systems coming up? If so, what will be the trend? Is there a trend for more and more nations to become inclined in freedom of governance, where the acceptability factor is higher than the non-acceptability factor accounting to coercive, subversive or indifferent acceptance? Besides the trends getting reversed, it could also mean that new systems may evolve that may include even global governance or protectorate governance.

What are the constraints a particular type of government faces with respect to maximising national security? This will be an excellent area of study. But it is applicable only if the objective of the government is maximising national security, which in most of the cases is deviated. The constraints can be seen only if the governments follow the path to NS_{max} .

Is national security independent of the form and type of government? Externally it appears so, but needs to be examined seriously. Every form of government can achieve it, each of them having the best form of governance. At the same time, it is the best form of government, that is to be identified, that could achieve the same result within less effort and time, the two major aspects of governing national security.

29.5 Summation

Research factors and questions if identified properly make a research disciplined, purposeful and to the point. The information thus gained becomes valid addition to knowledge in the field of research. The research proposed in this study is on national security concept and associated governance. In governance the support from research is for practical application on the ground. It is not pure academic or accumulating reserve knowledge. Research can be carried out prior to any decision-making process in governance. Decision making is the key in governing a human system. It is vital for a nation and its government. It requires information which may be managed through appropriate governance information systems. Much

information is required to arrive at the exactness of decision making in governance. National security concept is a labyrinth through which a government will have to negotiate under compelling circumstances. This calls for continuing research through various adopting various research processes based on the identified research problems. Research in national security is not only required in decision making for governance but also to acquire reserve knowledge for future governance.

Research in national security based on the concept explained here can provide answers to the government engaged in it to gain competitive edge over others and focus on the point of interventions at relative ease. Governance is a complex task. Marginal increase in knowledge relative to the adversities and constraints experienced in governance can provide good lead in the overall activity of governance. It calls for dedicated research activities under the direct supervision of government in national security matters.

14 factors have been identified for designing research questions. The factors identified should cater for both primary as well as secondary research. Primary research is when information is sought for immediate and direct action. Secondary research is where information is sought for input in primary research. The information gained through secondary research is used for primary research pending immediate and direct action. This is entirely the prerogative of the government. There cannot be any standard procedures or processes in research related to national governance. Research questions should be modified accordingly. For example, preparing for military upgradation is a secondary research in the facet of all elements and terrains of national security for an advanced nation. The information gained from the research can be used for primary research for information in decision making for an imminent operation. Similarly primary research in economic security may provide answers to a government, say, about the mode of privatising the banks in the country and the impact it will have on various stakeholders. This information reserved in the repository will provide support for primary future research prior to execution according to the policies of the government. Secondary research will have more possibilities in national security. It is a preparatory field as well as a repository of information or primary research for real-time decision making during interventions.

In all these arguments there is an assumption that the government and the governance are ideal for the nation and are professionally scripted appreciating the criticality of human well-being as the end objective or the goal of governance. This is not applicable for governments that play the game without or with a different goal post.

Chapter 30

Assessing and Indexing National Security

An index will only be as accurate as the assessment

30.1 Introduction

The opening quote is complete only when modified as “*An index will only be as accurate as the assessment, where assessment is possible only when the decision objective is clear and present whether real or abstract, but not unreal.*” This means abstraction has a place in national security and it is important to human system behaviour. The strange case of national security is hidden anonymously in this statement.

No one has ever seen it happening even in the so-called “golden ages”¹ in history, been sensually party to it, measured it or experienced it in any way so that the concept of national security can be explained critically to the point of understanding to someone who has no clue about the concept among those who govern and are

¹ Author's example for “unreal element” (see quote). Golden rules are unreal statements. Hence cannot be taken for assessments of national security or stasis of such nature.

governed.² Let alone indexing it. It is not a tragedy or a tragic case of human limitation or helplessness. It's a reality that, if accepted and challenged, can improve human well-being (HWB) by governance. And it will happen, anyway, as evolution moves forward though the human systems will surge as a whole—forward and backward with an edge ahead in each surge. It has to happen in the natural evolution of human system at its own pace and frequency if the laws of invariance and limitations are even-handed indicators. Clarity of perception can add the necessary driving force to the concept and its governance to move faster towards the goal.

So what is national security? One can't show and say to a doubtful seeker, "Hey, look, this is what it is." If that is so, can it be said that the concept of national security is a kind of Golden Fleece³ or a pot of ambrosia⁴ that doesn't exist as an achievable reality? But both, in spite of non-existence were notionally achievable as abstractions in the fantasy world of dream castles. It indicates human determination and perception beyond senses and beliefs. If so, is it like sailing east or west with a compass along the equator of a watery globe only to reach the starting point at the end of it all from the reverse direction, achieving nothing at the end except memories of a senseless, but beautiful voyage in tropical weather into the blank and repeat future? No, it is cruel and criminal to conclude that way as the intent at stake is human well-being, which is an abstraction of sorts in one way and reality in another, provided abstraction is not taken as totally unreal. It can be corrected if abstraction is neither real nor unreal. Is it similar to a virus that is neither dead nor alive? No, no; it's necessary to hold the argument at this point of exploration.

The term, national security, has been in vogue for more than two centuries at least.⁵ The concept, sans a moniker of any kind, was in place since the time humans lived in formal communions or systems under collective security extendable to

²The evidence for this statement lies in the fact that every government governs differently without a standard framework for what they are aiming it transparently. Destination is not clear and fixed. Governments get more confused than the governed by the demand on them limited by incompetence in governing.

³Jason and the Golden Fleece is part of Greek mythology current in the time of Homer around eighth century BC. In the story the protagonist Jason and his crew of the heroic Argonauts set out on a quest for the Golden fleece by order of King Pelias of Iolcus. The king wanted to place Jason rightfully on the throne of Iolcus. Jason finally acquires it. Here it is mentioned as mythical and abstractive.

⁴Ambrosia is the elixir of Greek gods and also popular in Indian scriptures as *amrut* (Sanskrit) that confer immortality to anyone if consumed. In Greek mythology it was brought to the gods in Olympus by doves and served at the heavenly feast. *Amrut* in India is a much older (*puranic*) concept where it was churned out of the ocean by the *devas* (the benevolent gods) and *asuras* (malevolent beings who oppose gods) (mythical anteforce ha have been productively used in the situation) together. It is narrated in *Bhagavata Purana*, in *Mahabharata* and *Vishnu Purana*. The mythological narration points out the wholesomeness of the ocean and the ocean property available for human well-being and sustainability and immortality of life by itself. In this study the Golden Fleece and ambrosia though separate in concept are brought together as unachievable targets but attemptable.

⁵Yale University proclamation (Chap. 2).

nonphysical security as apparent and perceived security.⁶ The origin of needs in humans should be taken as the day life proclaimed on them an exclusive survival tool—progressively upward intellect. Yet the concept has been a case of interest, talking point and goal seeking to all those who govern or were governed in a formal human system used as a way of getting their things done to survive collectively. But it lacked clarity and confirmation all along. This applies to the concept as it is believed to be by all throughout its evolution. The new ideas are framed in this study to extend national security concept to governance in a larger hope explained in the earlier chapters and discussed relentlessly and reiteratively so far in this book. At the end, it is sufficient to say one doesn't know the extent the concept can be assessed in a measurable manner. It is also true that this study is only a pointer in this direction. It is to be found beyond this book by serious research and studies which anyway is true for any concept in vogue for further enlargement. If measurability is the key point then the question whether the concept is real or an abstraction (similar to happiness) needs to be established first. Assessing a real concept from an abstract one may require following different procedures. In national security assessment it would be much more complicated. That is yet to be seen.

Assessing and indexing national security is a task that follows acceptance of the concept in this study as a wholesome process of governance towards human well-being, which is a moving target that shifts away proportionally to the move a government makes towards its direction. Hence the moves towards it are what invoke national human well-being in national governance. This is the part that needs to be assessed and indexed, not the moment of arrival at the destination since the destination is an abstraction but not unreal. The questions posed in the previous chapter (chapter 29) on assessing an indexing national security need to be appreciated accordingly.

Before getting more into the mud one may at least take a peek at the concept of tangible reality (Box 30.1).

Box 30.1: A Peek into Tangible Reality

Reality is acceptable as an existent but it may not be known in every situation. For example “why did somebody shoot somebody in a political scenario” or “what if god doesn't exist?” One knows somebody was shot and god exists in the perceived appearance. Otherwise the question cannot come. There is a bit of “now I see, now I can't” kind of hooky play in such statements. But they all exist and for a person determined or an assignee for the task the results can be achieved even if it is not real. That is tangible reality according to the author. It means tangible reality is achievable if the viewer can perceive it despite being an abstraction but not unreal. It is happening every moment in human lives. This is what a government can prospect and achieve in national security as part

(continued)

⁶The terms apparent and perceived are as mentioned earlier from Adler's concepts in human needs.

Box 30.1 (continued)

of the lacing mix to apparent security. It covers perceived security. That is called weaving by the threads of believability according to the author. Smart and clever governments can achieve it. Tangible reality is part of discernible truths prospected from facts.

30.2 Reality of Abstraction in National Security

Abstraction is not real. It is appreciated differently. The term abstraction has been used in this book to explain certain concepts that are in use but hard to explain critically with clarity. They are not physically sentient but can be appreciated consciously. Reality is concretely sensuous. It represents facts, but abstraction doesn't, according to common belief since the days of yore, when humans started thinking and falling into the well without a bottom in the mind somewhere close to what was depicted in the movie "300"⁷ into which protagonist Leonidas,⁸ the Spartan king, dunks the Persian herald out of rage.⁹ But in a well like that shown without a protecting parapet in the movie, death is certain; in abstraction the well is bottomless. That means there is no end to the fall. That also implies there is no death in a bottomless pit. Isn't it good news, pal? It is also similar to the statement "falsehoods are not truths." But such aberrations in perception and belief systems will continue never endingly in Leoni's well¹⁰ without parapet or, more than it, bottom. There is no QED once one dunks something in Leoni's well. Is that an abstraction? May be in one way for this study; the herald in this case stays an abstraction.

According to early writers, the doctrine that the abstract is unreal carries with it a belief in the inherent faultiness in the human mind to appreciate reality.¹¹ How much truth is there in this statement is a matter of debate. Knowledge-philosophers agree with it. It has to be true. But such debates are not necessary if one wants to count abstractness in a planned intervention in human system governance. There is a place

⁷Hollywood movie (2006). The movie was a fictionalised retelling of the Battle of Thermopylae within the Persian Wars.

⁸Leonidas I (540 BCE–480 BCE) was narrated to be a warrior king of the Greek city-state Sparta who faced the Persian invader Xerxes at the Battle of the Pass of Thermopylae

⁹This act of throwing the messenger of King Darius of Persia has no historical backing but is used in this study to explain about abstraction as an unreal but ever existing mental concept as long as the believer survives without unchanging belief system. This is a serious point in satisfying people by a government through governance.

¹⁰The term Leoni's well is used with total respect to the Spartans for their bravery and love for their country and personalised to Leonidas as epitome of those qualities as depicted though part fictionally in the film.

¹¹Sheldon, W.H. (1904). "Is the abstract unreal?" *The Journal of Philosophy, Psychology and Scientific Methods*, Aug. 18, 1904, Vol. 1, No. 17, pp. 449–53. *Journal of Philosophy, Inc.*

for abstraction within the factuality of results in governance. Abstract is abstract in national security governance. It has value for assessment. It is not unreal. But this finding doesn't apply to other subjects where it needs to be tested for results in application. Interestingly, knowledge in a topic need not be the knowledge in another. One can see it in everyday usage of semantic appreciation.

Philosophers of yore had generally mentioned abstraction is unreal. It is true as anything unreal will not be real. But what about those that are unreal in the physical world but hold the key in human system governance? There are many such things that a government will have to take care. If a statue is bleeding or drinking milk if you feed it, and millions are flocking around the miracle effigy with offerings, how does the government react to it? Is it taking it real, like the people flocking to it think or believe, or understanding miracles are unreal and cannot happen in a physically lawful world? Government has to react to maintain law and order and to appreciate the spiritual security factor but for the government the "miracle" has to be an abstraction not unreal. It is there, but not there.¹² Yes, opinions can change. One doesn't have to agree with the author. But the government has to agree with the people for their well-being as truth in national security maximisation.

It is all about reasoning intricately allied with the fluctuations of mind and intellect as one can perceive today. Deeper examination is not considered necessary as the topic here is about assessing national security for its results. The results are real and abstract. GDP is real as a product as well as the product of an accepted calculation, but economic comfort or peace is abstract. How can one link it? The accuracy of assessment depends on the metrics used and the outcomes assessed. Unreal will not exist but abstract may as a relative entity or concept of the human mind for which governance is carried out. If a person doesn't appreciate an entity or concept it doesn't mean that what he or she denied is unreal. The denial factor may be of something that exists as real or abstract in the perception of the mind and hence valuable in decision making. Assessment is decision making. There are results at the end of such assessment and they are critical for comparison with self as well as others for further decision making.

Abstraction is a noun in any language. A noun has to be a person, creature, place, thing, quality, state of existence, idea, quality, action. . . A noun is "something" with a name. A noun is not unreal. Darkness is an abstraction. It is not unreal. A decision to remove darkness has to consider it as something existing, though not real. This is where abstraction gets related to governance. This is also the background of polarities in human system. The reality perception is based on existence not strictly of something that can be proclaimed as real.

The issue with the concept of national security is that it does not follow the rules that are generally accepted in social disciplines seriously. First, it doesn't fall in any class of nouns as it covers more than one. It is real, unreal and abstract at the same time. Real because it is a goal, unreal because it is chased as something it is not,

¹²It is a kind of paradoxical situation that author Joseph Heller (1923–1999) used to highlight the paradoxical but logical contradictions of life in his satirical war novel *Catch 22* (1961).

abstraction because it is as an apparent goal mixed with perceived goal. Worse, it is a moving goal, something that can never be reached because of human vicissitudes where the end objective is not fixed or quantifiable. But that is not a problem in assessment. It can be assessed where it is as long as the nation and its government knows it has to move ahead—in the direction of national security in relative motion as time is a quantum measure that assesses through as a sign of change in entropy of the system.

In general, one has to conclude that the abstract is whatever “exists” exclusive of reality and unreality. The abstraction, hence, has to be visualised in isolation. At that moment it is real. But when carried with reality they become unreal. In such case they become firmly abstractive in a sentient whole.

Human communication takes a turn in verbal communication as it encounters appalling loss in sentient meaning with respect to the sender as well as the receptor. Each sender and receptor associated with the communication will have different perception. The difference in perception changes the significance of the message. So, imagine the seriousness of the task a government will have when it is the sender or the communicator and the population of the country as the receptor! The government will have a concept of national planning. But the idea takes a million¹³ formats when it is communicated to a million people, that too by more than one means of governance. This way a single communication format or information branches out into many formats, most of them transformed from the original, according to the respective receptor’s perception. Therefore, what the receptor perceives is not what matters in assessment. It has to be the relative assessment of the output with the original communication or intent of the originator. The important aspect here is that in assessment it is the result or output of the original idea that matters. So the output needs to be assessed relative to the original against the distortion in the perception of the people through various surveys and other assessment methods as considered fit by the government. The feedbacks from the public and their representatives such as media are welcome. The government should take them into account. But they are not the ultimate results. The perception of the people varies. Government is in a better position to arrive close to exactness of the results as outcome of its policy. The results are what one surveys or gathers from people. They will be different. Therefore the assimilation of what is gathered with the original is what one has to assess to arrive at the exactness of the result of an intervention. Is this difficult to understand? In other words, the originator or the sender is the only person who could decide the result of the input communication. Not the other party, unless the “other party” is the originator. This too is difficult to appreciate if one thinks in individual perspective. The “other party” becomes the originator when the party is an organisation which is an individual in legal and ethical concept. A government is such an authority. Hence the team appointed by a government becomes government itself that originated the policy whose outcome is assessed by the former. The government is the “sender”,

¹³Interestingly in communication the receptor as well as the sender will perceive a message differently in multiple ways. This is something that is not generally discussed in communication.

not the individuals in it. Hence the communication has to be seen as originated from government and, therefore, the government may be in a better position to finally decide the output for assessment. This can be concluded that the government is the authority that can decide on its quality and that alone can assess the national security achievement through governance not the receivers, the population who are the governed, though it is their well-being that is being assessed. This method, it can be criticised or commented, creates a situation. The public viewpoints need not be accurate for judging a government's performance. But that, if not true, will reflect on their decisions to choose the government again. It counters the situational dilemma. The public may not be satisfied even if the government does well. This answers why even the best government, according to governance, fails to come back to power. This is human psyche of needs and that being a special phenomenon is inbuilt by default. Hence has to be true and the only way one can believe here is that such a complex scenario is necessary for checks and balances for natural existence of a human system. Otherwise they will not continue. All these complexities only show that abstraction is in and national security is measurable within the real, unreal and abstract situations. But how to measure it is a question that the human system has to slowly arrive at in course of time by making adjustments in studies carried out along the time.

Therefore abstraction is neither real nor unreal. It is not something in between like a zombie word. Imagine a virus which the author not-so-firmly-yet believes is the life giver that came from a nursery elsewhere beyond the Planet and keep coming from within mutated and dressed well to shape and reshape life. The humans call some such arrivals pandemics. That is when there is a sweep through. Other life forms are not aware of them, hence have no names, though affected. This has to be visualised in relation to the terrains of genome and microbiome. But the viral metaphor is to say similar to things other than living or dead. There are also abstractions that are different from reality or unreality.

It is important to understand abstraction and its usage more than ever at the turning point of sapien well-being in the new century as the world is likely to speed up in top gear. The impatience is visible.

So, what is well-being?

30.3 Puzzle of Well-Being

Is the term “well-being” a puzzle? It seems to be. But a puzzle is not difficult to unwind. To appreciate and identify the metrics for assessing national security, the end objective of national security governance, the well-being of people, should be understood clearly. Besides, well-being is a moving objective. It is also the future. Prolonged future increases probability of malfunction. It is quite difficult to appreciate a moving objective exhibiting a confident teaser—“catch-me-if-you-can”, etched on it. But, if determined, it is possible to acquire well-being as a target of governance even if it is moving. Fortunately, the constraints are not governed by the

law of limitations. The constraints are external to it. That means they sure can be measured. What are the constraints? There are two.

The first constraint is that the end objective, human well-being, moves back when one heads towards it. That is why it is an inverse target. So there is always a standard distance between the target and achieving it. Second, it is still not clear what well-being means—the semantic dissonance makes it foggy. At this point the first constraint is temporarily suspended. People may define it differently. Hence it is necessary to standardise it if national security has to be assessed universally or at least with respect to the state.

The second constraint is actually the prime motive for governance, because the first becomes effective only if the second is critically understood, though mentioned in the definition of national security in this study. There is a huge semantic dissonance and deficit in universal acceptance and understanding of the common goal of human well-being. So the first attempt is to unwind the puzzle of well-being. The second is targeting it once concluded.

It is said human well-being is a broad concept that comprises many factors. That is when it is seen from the point of view of deductionism or deductive reasoning. Deductive reasoning is expected to lead the reasoned to the truth sufficient enough to prove the hypothesis, but not beyond for further refining for precision clarity to frame as a target. Reductionist approach may provide a better solution. Well-being is about “what the people need and want”, a question introduced in the earlier part of this study. The answer was “well-being.”. That is from where the quest starts. From his position it may be possible to identify the exact nature of well-being. If it is taken that people want their needs to be satisfied, the point raised by Adler comes to the fore, “Everyone wants more than what he or she needs”. So no one can have the needs fulfilled. It is seen everywhere in human construct and personality. So, a government cannot anyway achieve it as it becomes a chimera. But, if intrinsically explored, the researcher can hit a point in this lemma. The critical factor of human need is the point at which each individual deflects the needs in Adler’s posture: looking for further that the government cannot give. So a government can stop at a point short of the critical need factor for humans. In this explanation, the critical factor of human well-being is the point of need satisfaction stage from where the lure to go further deflects. That means no government should try to reach the critical point or yield point whatever it can be called. Here one may encounter another catch. The critical need factor may not be identical for each individual or group subject to differentiability in individual and group needs. This is one of the reasons for differentiability of opinions in public on government’s achievements. That is real and therefore presumed to be necessary for balanced governance.

Every individual as well as every group will frame their own opinion for human well-being. But for a government it should be pragmatic assessment of human system requirements. People’s opinions will be based on their perception of physiological and psychological needs that will be based on the conditioning factor of individuals as themselves or group embers. Here the government needs to standardise the human factor. Unlike the feed for an engine to run, the input for individuals has to be in terms of participation. The government is the provider. As a provider the

government should be in control. That is why governments have to decide on the specific aspect of well-being and the quantum of well-being for national security governance which is better through peoples' participation without either submission or dominance or any other reasons such as votebanking,¹⁴ power abuse, etc. The needs factor thereby can be standardised though it will be different for each geopolitical entity. In any case of dilemma, the assessment model can be a state either actual or imaginary.

The perception of human well-being includes many factors such as quality life, welfare, living standards, employment, money flow, activities, material well-being, income and consumption, interpersonal relationships, health, interactions of all kinds, safety, utility, development, empowerment, absence of fear and anxiety about life, spirituality, asset possessions, material needs, prosperity, growth, development and so on. Looking at the research on human well-being it can be concluded that the subject is still being explored and covers almost every field of study. That is natural because it is human specific. But what exactly matters to human well-being need not be any of the things or matters mentioned here but the way of optimising them targeting human well-being. Until the well-being concept is unfolded publicly it will remain a puzzle. The only boat to cross the mystic river at the moment is governance. Governance, for a nation, is an intervention in the public domain by the government. When it is in motion purposefully and solely intended for human well-being, the intervention triggers national security in single package. This, the governments have to execute through various dimensions called terrains by optimising the identified elements that remain together as inclusive factors of well-being, the end objective, the goal. That is how national security has been defined in this study in which the only aspect that is still vacillating is in the definition of well-being.

In this quest, as already mentioned, there were abundant studies to understand the meaning of well-being as the targeted end product or destination of the national security process. Being a human concept, it is what gives the ultimate psychological stability to human intellect to sharpen the cutting edge as a positive survival tool. It means the human mind, when under the feeling of well-being, is at rest with survival dredge and is at the minimum of survival emotions. This state being individual perception, a nation should have the standard average of the state of well-being. This average however is not possible to measure against any other format except for comparison. One of the reasons is that well-being should be felt with a feel. Terminologies such as health, happiness, prosperity, restfulness of mind by needs

¹⁴Votebanking is a term used by the author to explain governing by pleasing voters, if necessary even by violating law and ethical practices. It is a single word used by the author in line with mountebanking, another word that denotes unfair monetary activities. Votebanking includes privileges of inequality given to select groups, riggings and other illegal and unethical practices used in elections to gain votes. The term also means partisan governing by pleasing people who matters and gaining power through illegal and unethical practices in elections including rigging, voting in the name of dead people, confusing voters, preventing voters from reaching the booth, bribing, threatening, coercively denying individual thinking, and a host of other methods based on innovative ideas of subhuman intellect.

satisfaction and similar others are not sharp enough to judge accurately. Another lemma is that if individual well-being is the objective, it is not governmental function seriously as the individual too has to perform besides the person's behaviour as a group member or as the individual in the group too needs to be taken into consideration.¹⁵

There are many research works in social science that describe human well-being. There are domains, categories and subcategories of factors that contribute towards it. In one set of studies, the components explained are relationships with family and friends, emotional well-being, material well-being, health, work and productive activity, feeling part of community, and personal safety (Hagerty et al., 2001).¹⁶ In this, the researchers concluded that many of the indexes were successful in that they were reliable, had established time series measures, and could be disaggregated to study subpopulations. However, many fell short in four areas:

1. Indexes vary greatly in their coverage and definitions of domains of quality of life (QOL).
2. None of the indexes distinguish among the concepts of input, throughput, and output that are used by public policy analysts,
3. They fail to show how QOL outputs are sensitive to public policy inputs.
4. None have examined convergent validity against each other.

The authors further recommended research to improve them. Earlier in 1994 Cummins, McCabe, Romeo, and Gullone¹⁷ and in 1996 Cummins¹⁸ QOL has been examined for indexing. According to them while life satisfaction is commonly measured as an aggregate of individual life domains, the characterisation of such domains is uncertain. Third study grouped domains used by the Comprehensive Quality of Life Scale (ComQol). No difference was found in life quality between normative data and data gathered from people with a chronic medical condition, but people selected on psychiatric criteria had a lower life quality, most particularly in the domain of intimacy. It is concluded that life satisfaction, and therefore subjective well-being, can be economically and validly measured through the seven ComQol

¹⁵ It has been mentioned earlier that an individual is subject to three types of behaviour: individual behaviour, as a member of the group and as a group member but individual in behaviour. All the three behaviours are functions of time and therefore part of personality projections.

domains mentioned before: Material well-being, health, productivity, intimacy, safety, place in community and emotional well-being.

As the studies progress the list becomes longer. Diener and Suh (1997), Boelhouwer (1999), Marks (2007), Costanza, et al. (2007) and Flynn (2002) listed many potential attributes that included education, employment, energy, human rights, housing, health and health care access, income, income distribution, purchasing power; mobility; transportation, infrastructure, governing institutions, social participation, population, reproduction, leisure activities, sports participation and vacation time, spirituality, public safety and crime, traditional activities and cultural responsibilities among others.

All these show human well-being is not easy to appreciate or define objectively but people will have a fairly good idea of well-being as something which makes life worth living, more so when they do not have it. If it is so then it can be defined even if it is not attainable completely as an acquired definite target. In general the common nomenclature is what is accepted as something good in relation to identified domains such as family life, companionship, freedom to aspire, equity, equality, career possibilities, physiological need satisfaction, possibilities of psychological need attainment, limitation of anxiety related to future, safety and security and so on. Indicators connected to such domains and more help a nation or the human systems to assess their well-being and compare with others. But the problem with comparison is that the assessment may not be on standard format or a country-specific format may not be suitable for another under the differentiability problems. In other words the indicators connected in between will fluctuate between objective and subjective in nature and also between normative and descriptive prescriptiveness. The issue here is such assessments though may give fairly satisfactory indications of national security may not be sufficient for framing the national security index unless the process of quantifying well-being is standardised.

Indicators are the actual measures of a concept or an idea that leads to a result. Indicators need quantifiable attributes for measuring results. A set of easily quantifiable attributes that represent the entire system concept will be very supportive not only to measure the performance but also for progressive research study to refine the performance measurement yardsticks. Every knowledge discipline, whether science, art or both uses indicators. They keep on changing based on continuing research. Indicators have been the subject of considerable discussion every knowledge discipline. The indicators will be based on the approaches adopted in a particular discipline. A target like well-being falls in very discipline. This will be clear observing the elements of national security. Understanding well-being, therefore, needs a multidisciplinary approach and analyses of applications. It has to be, if not exact to the world view, at least close to it. This can be achieved by applying correction factors of standardisation when comparing one with a not-exactly-similar another. National governance will require an exclusive formulation of result assessment for indexing. This demands national security indicators. Not transfer of other social indicators to arrive at the NSI.

The puzzle of well-being can only be uncovered by understanding that it is not yet understood, but widely used in every forum where human concern is exhibited, more

so, in public. It is also accepted that human well-being is difficult to define and measure objectively and can only be categorised in specific niches of human aspirations and perception. Following statements stand in support of these hypotheses:

1. Well-being is a mindful feeling of humans (not exactly one among other “human feelings based on survival emotions”) when the mind appreciates the existential situation positively. This feeling, therefore, varies from person to person as it is individual appreciation that too as a function of time. If it is a function of time then it is situational. Since situations and humans are oriented differentially at all times an exact definition of well-being is not possible. This is how the world arrives to the conclusion that well-being is indefinable.
2. Well-being is about living a quality life. This term quality life is frequently used in corporate governance. It can be applied to a nation where its people live qualitatively. Good life depends on state of health, happiness, spirituality, contentment, affluence, prosperity and many similar conditional situations that cannot be measured to arrive at a fixed quantum.
3. Well-being also means or can be ruled that a set of people are living without any kind of deprivation or anomalous dependence. This doesn’t mean they are ultimately satisfied but could be said to point out they do not lack the essentials for a good life. This means all the provisions are available and it is the use that matters. This makes defining well-being difficult as expressed in the hypotheses.
4. Well-being is a dynamic process hence is indefinable. It is true that well-being is dynamic as it is a function of time being a process feeling of humans in a human system. A dynamic process can be defined as a process but not as a target. In the process of life humans go through various interactive matrices that will take them through different corridors with different experiences which may contribute to the feelings of wants and needs that are satisfactory or unsatisfactory. Focusing on just the well-being therefore can only give vague explanations of something that is felt good or bad.
5. Another way of looking at well-being is as an expression more than a feeling. People often express it even through protest projections.¹⁹ It means many of the social disturbances and protests also can project the underlying well-being.
6. Is well-being tangible? The answer to the questions always ends up in the negative and confirms it is a pleasant sensation of the mind. The studies on well-being are still continuing. It seems to be difficult to come to a possible conclusion. Under such situation it becomes a tangible concept.

¹⁹Projection means the way a person projects his or her personality through the activity with direct and indirect reflections. A personal attack is a projection of anger and so also sloganeering with raised fists or wearing a body sign as black badges or bands seeking individual and group freedom. Freedom to protest is a powerful sign of well-being and protests project that freedom. Violence and riots in some parts could also be a sign of well-being. But the projections need to be analysed carefully before any conclusion. Writing can project the personality of the author more than the words in the book situationally. Yes, this book too.

7. Many scholars believe that well-being is related to progress of human systems. It is acceptable as progress improves QOL. But, if well-being is not just quality of life then the probe gets restricted. Besides if progress is a measure of life it will lead us to the conclusion that earlier human systems lived in absolute gloom and melancholy and the future will be more attractive than the present. Heuristically it is not possible as no studies have been carried out. It is true that the present scenario of the world shows collectively the population is poised well towards well-being. At the same time the anxiety of the future about sustainable lifestyle and thoughts about the coming generations upsets the argument that future will be better. There was no need for sustainability goals and similar plans if time brings progress and progress bring well-being.

All these statements and more, if one searches further, will only make the task of dealing with human well-being more confusing. Instead of concluding well-being is a feeling that involves subjective as well as objective factors along with normative and descriptive attributes related with life and its existential formats, it will be easy to appreciate the concept through own perspectives by an individual as a wake up thought every day to see whether the day is welcomed or the thought behind is that it is going to be yet another day. This is especially so when the study is about governance and national security. How does a citizen feel under the government is ultimately what defines his or her comfort in society at particular moment or period in time. In a casual but academic enquiry by the author in many situations, for a prolonged period of nearly three decades, in social and work situations the answers received from individuals in live situation without knowing the questioner was serious but under a pretext of normal talk it was surprising that none of them ever thought the situation concerning to self but answered as if it is the other person's concern and on behalf of him, her or a group. Such attitude of people, commenting for others keeping self-separated from the answer is quite an interesting find, especially in a world where people complain for lack of human concern and compassion. The complainant is proxy especially when it was about perceived security.

The puzzle of well-being lies in the human projections within a country. Criticisms depending on age, career, health, financial situation, public life and so on for and against a government are indicators of the feeling of well-being of people. In this case even the casual comments are important. The media will reflect majority views for and against governance based on their axial preferences. The views may lack serious research. It is important to understand here that anything against governance or in favour of it need not necessarily reflect the exactness of human well-being. It is not the individual appreciation of personal well-being that matters in national security but the individual well-being applied and adjusted with social well-being and averaged for the period that matters as the factor of well-being. The human system is more important in governance than the individuals forming the system.

The puzzle of the well-being ends when it can be defined. While the term is commonly used in individual sense, it is difficult to define well-being in a universal mode applicable to individuals. Besides, it is relative to individual and the way he or

she feels it. But it is certainly possible to define well-being, the moving target of national security governance in the perspective of a government and thereby a nation, the human system, the government is expected to govern. This study defines human well-being conditional to national security governance as follows:

Well-being, as the **ultimate objective** of national security, is the achievable extent of **existential wellness** that a government is accountable to provide by governance to the citizens of a nation, assessed in accordance with the **maximum constitution** among the group of nations and other geopolitical entities, in terms of human comfort sans interference of any sort to **human freedom** and constitutional rights, where,

- *Well-being means the apparent well-being a person or a group should feel for self-actualisation in his or her activity without total negligence to perceived security.*²⁰
- *Ultimate objective is the goal of governance as acceded within the SNS.*
- *Existential wellness is the feeling of goodness in intrapersonal and interpersonal survival of an individual citizen with the confidence of facing existential dread where existential read is the fear caused by survival emotions natural to all individuals.*
- *Maximum constitution²¹ means the most complete Constitution whether written or otherwise followed by the geopolitical entities at a particular time taken as standard for the period that provides for maximum well-being as per this definition.*
- *Human freedom is the freedom of life and living that a human is righteously entitled by birth and not restricted by constitution or any other form of human induced regulations as long as such freedom doesn't interfere or disrupt the exercise of similar freedom by another human or human groups whether awarded by the constitution or other humanly induced and accepted regulations.*

Well-being is not a puzzle, but there is puzzle in the well-being mainly due to its abstraction. But the question is, why measuring well-being (Box 30.2).

Box 30.2: Why Measure Human Well-Being?

Measuring well-being is necessary to calculate the national security index as a means of appreciating the result of governance towards maximising national security. Here well-being is not a product that people hold but feel, hence uncountable for quantum assessment. The feel too will not be uniform or time constant. Therefore, it needs to be measured as an output of governance by assessing the results of governance and not by direct survey among people. It has to be done with a system organisation that can assess the governance format competently and realistically for desired results and should not be part of any other need or impact assessment setup. Today the world understands there is a greater need for indicators measuring human well-being due to the limits of available indicators of economic performance and social progress.

²⁰See Paleri. P. (2020). *Human investment management: raise the level by capitalising human*. Springer Singapore Pte Ltd. for more on self-actualisation.

²¹To further amplify maximum constitution is an expression used here depicting the constitution that is as close as possible to the well-being of humans taking into consideration that they are the most advanced in nature compared to other life forms but with a fragile sentient sensuality to life and therefore need to be governed with care and attention more than any other life forms in existence.

30.4 Signs of Well-Being

The signs of well-being are trailed from the definition given in the previous section. If that is what well-being is then the factors that will contribute to an individual's well-being can be identified by means of the following methods:

1. Direct assessment.
2. Projective assessment.

In **direct assessment**, the teams involved could scientifically assess the factors of well-being to the standards decided by the governing system as appropriate. In **projective assessment**, the scientifically trained projection teams could carry out the measurements and appraisal. There could be conflicts because the opposing representatives may challenge the government's findings. Interestingly these challenges and their counters together can be used very effectively as projections. The global authorities can also see the progressive assessments and arrive at their conclusion on the factors of well-being applicable to that nation. It is not necessary that there will be identity of mind about the findings. But the nations could conclude the finals based on the findings as per the determined standards and correlations of factors. The factors of well-being when concluded with techniques of measurement lead to the national security index. The factors recommended are the following²²:

1. **Freedom.** Freedom is the frontline sign of well-being in a human system where one control another unlike in any other life form. This is the direct result when intellectual prowess becomes the survival tool. The enslavement wherein freedom is taken away starts within own species at the bottom. Only humans enslave.
2. **Prosperity.** Prosperity is the general trend of lifestyle which is quality based, not expenditure based. Prosperity is the degree to which poverty (eradication of which is the goal #1 of SDG—no poverty) is absent.
3. **Health.** Good health and well-being is the goal #3 of SDG where well-being is mainly physical. Health as a factor of well-being in national security studies means absence of ill health including physical and mental traumas.
4. **Money flow.** Money being the prime barter instrument, its positive circulation²³ in the human system is indicative of many aspects such as personal income, purchasing parity, living standards, consumption rate, wealth generation and so on that induces feeling of well-being. There are many indicators of money flow in a human system including expenditure in many formats both public and

²²There are many research reports and commissions on the concept of well-being. The factors presented here are based on the studies exclusively on the national security concept identified and defined in this study with a global acceptable indexing for comparative analysis and followership for the overall global application towards global human system benefits. The concept however doesn't cover governance in the global context. National security is the gold of national governance.

²³Positive circulation means flow of money recognisable and acceptable to the government. It is normally the flow of white money.

private. The money flow basically projects the velocity of flow of money, as mentioned earlier in this study, in the system.

5. **Resource synergy.** It is primarily the availability of resource that a country needs from onion to open spaces. Absence of onion in the market can make people think of doom in India being a prime food source; onion price rise can spell disaster to the political parties in power. A country without open space to hangout will find the anger level high among the public, though they may find submissive.
6. **Safety and security.**²⁴ The anxiety level is an indicator of the level of safety and security in the human system. This can be evaluated in many ways—from complaints, projections,²⁵ and drug usage to pharmaceutical consumption irrespective of social status and age and other ethnicities.
7. **Knowledge.** Knowledge is the ultimate fuel for the intellect as the survival tool. But dark knowledge, the knowledge that is corrupt, can damage the mind and the thinking process like an adulterated fuel damaging the engine. Knowledge provides repetitive strength to the neural intellect. The right knowledge is knowledge here. Knowledge is what makes a person the knower²⁶ not a know all.
8. **Information.** Information here is the right awareness of the people about happenings in the system they belong. A well-informed people will have a better functioning government. It will mutually enhance the governance and the system.
9. **Controlled emotions.** The public behaviour can be emotional. It is easy to appreciate controlled emotions.
10. **Rule of law.** Rule of law establishes obedience to law and also indicates the crime rates and social disciplined.
11. **Changing governments.** In governance there will be frequent calls for changing governments but it is the frequency of actual change that indicates the stability of governments. A stable government is a better sign of system well-being.
12. **Conflicts.** Absence of conflicts indicates a system that is trouble free and balanced.

²⁴ At this stage it is not clear whether safety and security can be separated because both are intertwined by usage, though not by experience and practice.

²⁵ The mask in Covid pandemic or the need for a magic mask for a person to overcome his insecurity as represented by the protagonist in the Hollywood movie "The Mask" (1994). Even Zorro's eye mask in the movie (?) projects the fear of facing the world in the anxiety to conceal it even though he is a superhero. This tendency is in every human. Absence of it shows safety and security.

²⁶ The term knower is taken from the Bhagavad Gita where it means the one who "knows" the truth and realises knowledge. In this study the author's interpretation is that "knower" is the one who knows sans dark knowledge where knowledge is compared to light that doesn't lose brightness by sharing it. And is also shareable without guarantee that what shared is what accepted or conceived by the other.

13. **Longevity.** Mortality, morbidity, DALE.
14. **Political energy and synergy.** The vivaciousness of the political system indicates social well-being. This can be accessed and assessed from the political conflicts, complaints and general behaviour in the legislature and public behaviour of politicians.
15. **Social interactiveness.** Social interactiveness sans ethnic separations is a good indication of well-being. However, this will not be taken without applying correction factors in multiethnic system and thereby is related to ethnic security element of national security.
16. **Equality.** The factor is hidden in this ethnic security optimisation. People are treated equal in matters human under equality.
17. **Equity.** Measure the deficit at random and never in a selective mode. There is nothing alarming if the financial disparity is vast because it is also an indicator of done flow and the available supply head maximum. In an equal system the gradient is minimum.
18. **Welfare state factor.** Subsidies, doling, etc. are negative in assessing well-being as they indicate it is a state-supported welfare society. It also means once the state withdraws it will be anarchic.
19. **Continuum factor.** Continuity of human system is another indication that the past was good and present is better. Without such difference in gradient well-being will not sustain. The main objective is the present moved towards better from the past? If so the future can be better than the present. This is a feeling that the people get towards well-being.
20. **Sensual humour.** Well-being is about individual feeling within a human at any point in time. A smile on the face can express wellness in totality. It can also express momentary happiness. Wellness is longer lasting. A major difference between humans and other life forms is the ability to smile and laugh cued by sensual humour. Sensual humour cannot be appreciated in an environment of ill-being. The level of sensual humour prevailing within a human system is passive indication of the feel of goodness in it, where sensual humour is the human ability to experience humour sensually in totality. In such system humour will prevail. There are many other indicators of humour or its absence in a society. It could be observed directly as well as indirectly through various projections in the system. These are not amplified here. Empirically sensual humour within a select human system can be observed by anybody to understand the breeze of well-being around. Humour can survive even under extreme survival emotions such as anxiety. The canvas is well-being. Sensual humour is author's special choice as a metric. But its incorporation as an NSI metrics needs special study.²⁷

²⁷ It was reported that popular Afghan comedian Nazar Mohammad aka Khasha Zwan was taken out of his home in Kandahar province on 22 July 2021 and brutally tortured and killed by the Taliban. This is a sign of inverse relationship between sensual humour in society and ill-being of people. Mishra, S. "Taliban admits it killed Afghan comedian after video showing capture and murder go

Many more signs can be identified depending upon the characteristics of the human system. They can be identified, appreciated and introduced in the assessment of well-being. There are also factors and aspects that are considered to be signs of well-being which actually are common factors in any human system whether there is organised governance or not. It is also not easy to measure it with respect to a specific factor. One of them is happiness which is a human condition not related to governance. Such indicators act as proxy. All the identified indicators could be combined into a composite indicator to identify the well-being quotient in a human system either for the whole country or individual units such as states in a federal system, within it.

30.5 Mathematics of National Security

Mathematical aspects of national security can be topics of significance for assessing national security index (NSI). The idea of NSI needs universal acceptance. “How to measure national security?” is a study by itself. Once this calculation can be ascertained, a nation by itself or the world community through international bodies can assess the NSI of a nation accurately for a particular moment in time, any time. This will support governance and self-monitoring of a state rather than becoming political slogans for the purpose of winning elections. Individual citizens will be able to monitor national governance and provide support by positive participation. Such comparisons will make people more powerful, aware and knowledgeable who in turn can demand national governance to move forward in national security through right of information and opportunities for information. That will be empowered governance with people as stakeholders. Such governance will trigger refinement of governmental systems. People will be able to steer their well-being accurately without being influenced by variant information as they know where they are. NSI will bring power by information to the people and the information will not be by propaganda, misguidance or belief systems. There are no national indices today that can give the exact value of national security—total well-being at a given point in time of the nation. The closest for external observation is the human development index (HDI) that too an international assessment scheme based on variables that have no direct relation with the concept explained in this book on national security. HDI is rather a common figure that does not directly reflect the human feelings in a country, though gives a rough indication of their well-being. The HDI also presumes that, if a country is developed, the people will have a sense of well-being. It is only partially true. But there are countries that are less developed where people avail the same quantum of well-being. It is also true that the well-being of people in a country that has advanced HDI varies among people to people especially in differing ethnic

viral.” <https://in.news.yahoo.com/taliban-admits-killed-afghan-comedian-054516232.html>. Accessed 01 August 2021.

backgrounds. While there are many examples that can be quoted, the easiest and most comfortable example is about the ethnic divide of the rich and the poor in a country. The parameters of assessing the NSI are also with respect to their changes in the future perspective. The elements and their inter-relativity are serious topics for research in relation to the NSI.

30.6 Identifying Assessment Metrics

Assessments include measurements which need the metrics to be appropriate. But, a metric can be inappropriate. Whether measuring the length of a coastline that is altering at every moment, assessing a movie for its popularity, a book to review, or comparative assessment between to poll candidates there could be prejudicial opinions and leaning. Such measurements can end up in disputes as relative to something or someone. Hence methods of measurements and actual measurement should be consensual to all who measure the conceptual result. A measurement can be a fractal. The exactness of fractals is that “the assessment will depend on the scale” where the scale is the metrics. Under the fractal theory a metric can give a different result from another if used to measure the same conceptual result.

Every yardstick and metric is incomplete. There are many things in reality, unreality and abstraction that are what they are and better left without measurement. Like the song of a bird or the soft cry of a baby. Or the feelings that a morning sun creates in the mind compared with that of an evening sunshine or the picture of the sunset. For example, take the colour of the ocean. It is said to be blue. But actually it is not the colour of water. Water is colourless. The term blue planet or blue marble are wrong from the point of view of measurement. Ocean reflects the key which predominantly refracts the blue spectrum of the sun's rays during day. The earth is not a marble in shape. It is not even round or spherical. It may look an ellipsoid or potato if it is gravitationally assessed. But from outer space the water-filled part of the crust makes it resemble a marble with a bit of poetic licence to forget the projectiles. Therefore, any measurement is in appreciation laced with human licence to see and add a bit more under bias. Unfortunately, appreciation cannot be made into a scale for reality assessment.

30.7 Then Comes Ockham's Razor

An interesting principle that could be employed in the assessment of national governance and all things associated with it is Ockham's razor. The principle states when there are more than one solution or answer to an issue or a question, where all facts are accounted for, the simplest of all could be more likely to be the better one. The principle is applied to a wide range of disciplines. Heard about seeking the second opinion in difficult situations? Well, the principle has many meanings

depending upon the interpretations. The author's interest in Ockham's razor is not to shave with it but to poke the puzzle hidden behind it for application as a law in the assessment of facts. It is not attempted here. The principle says it is better if entities are not multiplied without necessity. Frugality in decision is a format. Ockham's razor advocates cutting the superfluous to make it simple. The principle also advocates that one gains nothing by complicating an explanation without some corresponding increase in its explanatory power.

Ockham's razor is considered a law of parsimony. Parsimony is a philosophical term²⁸ for a kind of miserly behaviour—the unwillingness to spend money or resources. It is extreme frugality. The principle is attributed to William of Ockham (1287–1347) Surrey, England. He was a Franciscan friar. His statement can also be interpreted as “plurality must never be posited without necessity”. There is also an opposite of Ockham's razor that the practitioners of national security may understand. It is called Hickam's dictum as a counter argument to Ockham's razor applicable to medicine which says a health complication can be because of many diseases. According to those who argue against Ockham's razor the world is becoming more and more complex that doesn't permit chipping off solutions for complex problems. According to Hickam's²⁹ dictum, in such complexity, problems may have more than one cause.

Box 30.3: Ockham's razor and national security explanation

Applying Ockham's razor to national security studies is possible. Here the author's argument is that life and its laws and principles are simple. This statement is based on the observations of other life forms including plants and microbes. There is a tendency for humans to look down on them without realising it is the same (magnificent and amazing)³⁰ force of life that is also active in them (Chap. 23). The approach of these life forms to live a full life is not complex. Life is a unitary phenomenon; therefore this statement should be applicable to humans too. But it is difficult for humans including the author to explain a topic in a simple way and make others understand, probably, because it is too early for the first generation of the intellectual tool handlers—the humans. They are not wired for understanding simple factors. It should happen slowly by evolution. That is why simplifying the theory of well-being and achieving it through governance is advocated by optimising elements and

²⁸ Author. The link of this metaphysical minimalism with psychology is less relevant.

²⁹ John Bamber Hickam, M.D. (1914–1970), Chairman, Department of Internal Medicine, Indiana University at Indianapolis. Hickam's work focused on the physiology of cardiopulmonary disease. The medical principle “Hickam's dictum” (“Patients can have as many diseases as they damn well please”) is attributed to him. https://siarchives.si.edu/collections/siris_arc_393660. Accessed 20 October 2020.

³⁰ An explanation *a la* Ockham's razor. Was this shift necessary to mention this simple statement?

Box 30.3 (continued)

integrating terrains. The action is for the governments to perform. Their choices are open. That's it about national security—snipping the bits with Ockham's razor, simple.

30.8 Deadender Factors of Assessment

According to the author a deadender indicator is an acceptable indicator, but of no use being a deadender *ab initio*. It cannot be even trimmed by Ockham's razor to arrive at simple solution, because it is gone and disappeared but for the name. There are many deadender factors in circulation as indicators while assessing human stasis including well-being. These indicators are based on centuries old human belief systems where the exact origin and archival periodicity of them has never been examined before coming to the conclusion. They include happiness, love, joy, peace, honesty, cooperation, companionship, good Samaritanship, activism, confidence building, freebies, welfare state, soft power... There are many such indicators repeatedly used to assess the state of a human system. The results can be far from real if a deadender indicator is used for reality assessment.

The term deadender in national security is about sticking to a particular format of assessment without seriously thinking about its feasibility and suitability for the demanded action but based on the method inertia associated with such indicator or idea has been the practice in the past hence it continues today and will go on tomorrow also. The deadender principle is clearly visible in political scenarios. There are leaders who change political parties, but there can be voters who won't follow the leader and change party. They will remain in the party. it is deadender behaviour. It is quite visible in the political scenario in India. The particular follower may not leave the party and choose a better one even if he or she understands that the party is not doing well. This deadender behaviour, which may be called loyalty in politics, as the principle of assessing the suitability of a party for national governance is actually a deadender, a factor that is outdated but continues. Deadender factors are not suitable for future because they are already gone into history. In such case the situation offers no prospects for progress or improvement. The deadender factors, if applied to, can wrongly assess the aspects and prospects of the conceptual aspects of national security and results of national security governance.

30.9 Indexing National Security

Indexing national security will demand indicators of human well-being as defined in the concept and ways to measure them. The indicators of national security are the pointers of human well-being attributed to national governance, which means they

are tested and identified as the outcome of governance. The indicators will reflect people's circumstances in a human system, a nation in national security at a particular time in the history of its governance. This calls for continuous monitoring, controlling, surveillance and responding.

There are various recommendations for social indicators based on social sciences and associated studies. Social indicators are societal measures that reflect people's circumstances in a given cultural or geographic unit. In one of the studies Land (1983) identifies three primary uses for social indicators: monitoring (i.e., reporting for policy assessment), tracking (i.e., reporting for public enlightenment), and forecasting.³¹ These are given in the Puget Sound Science Review based on individual-centric appreciation of HWB. The HWB based on governance has to be assessed for NSI as it is about the performance of the government and national security. HWB is the target that too from the maximisation point of view of governance suitable for indexing national security as it is assessment of governance outcome based on GBNS. Seeking individual opinion is not a metric for NSI. Social indicators focus on populations of interest. Not the government. Social indicators may look at people differently in clusters of the aged or elderly, differentially abled, demographically lesser ethnicity (the word minority is not used here), or women.

There are two types of social indicators for measuring human well-being in direct human-centric approach: objective and subjective indicators (Diener and Suh, 1997; Costanza et al., 2007; Cummins, 2000). Objective indicators are those that can, in principle, be measured and verified in the "public domain", as expressed by Cummins (2000).³² Examples of objective social indicators include infant mortality, doctors per capita, and longevity (assessed for the health domain); and homicide rates, police per capita, and rates of rape (assessed for the personal safety domain). Objective indicator data can be gathered by observation or other forms of impersonal measurement, or by surveys that seek objective information from individual responses. The key feature of an objective indicator is the perspective: In principle, they measure attributes of human well-being that are publicly visible and have a uniform interpretation across individuals.

Objective social indicators help to understand how specific communities utilise resources or interact with the environment. This approach can be compared, though not closely, with the apparent security result assessment in the national security perspective of the government. Subjective social indicators attempt to measure psychological satisfaction, happiness, and life fulfilment, which are private attributes of HWB in the sense of not being capable of independent observation and verification. This can be compared with perceived security perspective but not exactly similar. This is the approach when human-centric well-being indicators are searched for. But for government and governance-centric approach that is suitable for NSI without prejudice the apparent security results are the objectivity in measurements

³¹ Section 3: nature of human well-being. Puget sound science review. <https://www.eopugetsound.org/science-review/section-3-nature-human-well-being>. Accessed 20 November 2020.

³² Ibid.

whereas perceived security becomes the subjective results. This is obviously more difficult than human-centric approach.

This in a nutshell shows the indexing of NSI has to be based on the results of the governance-centric approach of the government and not on the human-centric approach as in social sciences. The former is less corruptible or prejudicial and wider in scope for NSI showing the results of government that are considered catalysts of human well-being. The results considered suitable for maximising HWB are to be considered in appreciating NSI. The output of the government is more important than the opinionated views of the people assuming the former has well-crafted SNS and NSS for intervention.

The indicators for NSI need to be gathered through various surveys and research procedures by expert agencies in public as well as private domain exclusively identified for the purpose. The reality perception of the study would be live all the time. The study should be ongoing which will critically examine governance moment to moment like the flight controller watches the flight like a hawk from take off to landing. But in NSI studies there is no beginning or end ideally. It should be continuum monitoring of the nation once introduced through governments and their governance. It has to be continuous survey for the duration of governance and not periodic as if on a passage that halts in between. The results of the survey should be appropriate to the time when examined, hence the latest. NSI is a value at a particular time in the nation's period. It is a drive through governance as it happens without stopping even when the governments change. It lasts throughout the continuum of the nation. It is not specific to the type and nature of government, but monitors results of governance to assess well-being indirectly. There is no direct assessment with the subjects through the survey. This avoids major bias. There is no room for prejudice in the survey.

In human-centric approach too direct monitoring of key social and psychological states will be necessary for an understanding of social change and the quality of life. In governance-centric approach direct monitoring focuses on results that are expected to provide human well-being. The results achieved by different agencies need to be compared and amalgamated with necessary factors of correction before concluding the NSI. Considering that these procedures are not yet introduced in the world today interested nations themselves can carry out studies in NSI for internal assessment and also studying about other nations relative to one's own using the national security indicators applied to own survey. This way a nation can appreciate its position vis a vis another for applying to its own NSS if required. A global assessment may take longer time for universal acceptance of the idea. But it has to come if governments want to know their own sustainability and nations want to know the state of their position at any given time in the continuum.

Choice of indicators may depend upon the prevailing global environment though not exactly similar to the idea of welfare state propounded by T.H. Marshall based on democracy, welfare and capitalism. It was not a global and perpetual idea. While all forms of governance other than anarchy is democratic (meaning through an agent with people's participation by acceptance or non-acceptance) according to this study, the idea was meant for the capitalist world which a part of it was not. Among the

three, welfare was not defined but understood under perceptive reservations. It was applicable to the then situation (the orderly disorder of world war) and for the period of the prevalence of that situation. After that the term lingered on but the idea changed from what Marshall propounded and turned to the idea of free dolling for political survival. But traces of welfare state will continue as long as the governance systems continue in whatever form. The difference will be every system will have its own idea of welfare state. The national security concept of well-being is a different take and suitable for assessing human well-being not welfare. This is based on the assumption that the world is evolving into a more coordinated and responsible human system that is not likely to meet with serious apocalyptical and inhuman jolts in future. Instead the world is expected to be a better place than it was yesterday.

Indicators identified for assessing evaluating NSI should be related to policy and governance results. They may change with experience of governments and further research on the subject. They may not be acute but will not be biased if supporting correlations between the well-being yielding results and actual feelings of the people are identified through research. It is only for comparison in the beginning and application once the firm correlations are established. It means the procedures for identifying NSI will continuously evolve through the periods. It is a healthy sign. Falsifiability in a system allows for its evolution and improvement in a continuum, Nations, national well-being, national security are evolving systems in a continuum. Therefore it is necessary the NSI too evolves with time.

This study does not consider human well-being is complex. It is all the time there in human existence. Humans inadvertently and most of the time subconsciously contribute to their own well-being even when down and under through perceived security. Otherwise they may not be able to handle issues that mask the benefits of apparent security yield. Self-contribution to well-being is an added advantage to governments to govern. Governments primarily focus on apparent security of needs satisfaction. The problem is that the humans do not feel apparent security is sufficient. They need identity and more to get along in the system. How sufficient is sufficient, therefore, becomes the critical question in life. That is the reason why the idea of NSI is recommended to be made free of humans, though meant for their well-being. Therefore, it is the results of governance that matters. It is the results that are processed and refined to identify the quantum well-being not by discussions with people as the direct subjects. There will be enormous prejudices if made the approach human-centric, hence totally rejected. The yield and the results of governance will decide human well-being under. The idea is to identify indicators that will correlate the results with HWB to arrive at NSI. Identifying the exacting indicators of HWB based on governance results will be a challenge though tractable and equally daunting in principle.

30.10 Summation

National security assessment is complex, but practical, and not as mysterious as the concept itself as explained in this study and very pragmatic and positive for humans to venture. This may sound contradictory raising the question how indexing a complex subject can be pragmatic? The answer is that chasing a moving target is by heading in its direction without deviating from the course and losing sight of it. The vector of approach is kept always in the direction of the target which remains perpetually equidistant irrespective of the rate of change of momentum of approach. The target is acquired and never lost. Holding the vector precisely homed on to the target at all times is the challenge of governance. The quantum of momentum is not. Most of the governments make this mistake either by speeding up or deviating and detouring. Worst is when the government goes towards misidentified target, that too at high momentum. National governance even on fast track but deviated from the target of national security is worse. The fast track or increased momentum does not take the nation towards the target faster as the acquired standard distance remain unchanged on an equidistantially moving target. Human well-being is such a target. It is the direction that matters in GBNS; not the vectoral momentum. In fact increased momentum can cause stress. Reduced momentum may pull backward to the advantage of the competitor but still preferable than deviation. Deviation from the target is assured failure. Therefore, governing towards national security without losing target at the “natural frequency” relative to the nation as applicable to the continuum factor of the nation is the most appropriate way to govern national security. The result can be assessed by favoured global metrics or national metrics for internal use to handle the complex subject of national security. The momentum is gained through governance and associated interventions. Throughout one has to understand that in sustainable national governance the target is human well-being, the ultimate goal or the end objective of national security. It is a continuous process.

This means the success of national governance needs to be addressed by assessing the stasis of human well-being at any given time. Well-being is a feeling associated with emotions of the people in the concerned human system. It changes every moment. It may even reflect in stock market fluctuations. According to the author an incremental well-being can cause an incremental rise in the browsers. It need not be exactly the other way. This is not tested but may be taken as a hypothesis. Well-being will not be uniformly reflected; it is individual feeling that to some extent is contagious. Therefore the metrics for measuring the well-being should be compatible with individuals as well as the groups. That is why national security needs to be assessed. This can be done by globally accepted methods and also by nationally accepted procedures. The nationally accepted indices are the first to be assessed. Thereafter it should be applied to the globally assessed methods for comparison of governments because each nation is unique in its characteristics that range from its continuum position to the final stasis of governance at the time of assessment.

Part V
Future of Governance and Human
Well-Being

Chapter 31

Beyond National Security: Global Perspective

The clash between singularity and differentiability among humans will decide the global combine towards human well-being, subject to the two principal laws of life: law of invariance and law of limitations

31.1 Introduction

The purpose of this study is to explore and analyse the conceptual appreciation of national security in almost simple terms without including the complexity of research limitations and processes. The objective was to make the study appreciable to those who may like to enquire a bit more of the concept of "governance by national security" (GBNS) or national security for the ultimate objective of well-being of the people of nation—the citizen population from the "governing to the governed".¹ Therefore, the concept is shown in a shade deductively and reductively as elements operable in integrable terrains. The concept of elements and terrains are variables and can change in future, though not expected in the near future or at least during the span of life of the present generation.

¹The caveat here is that the statement is incorrect in the sense that the governed includes those who are governing also and vice versa in any form of government from the human system perspective.

The presumption in this study is that the overall purpose of human system governance is human well-being. If it is not, the study and the associated arguments will fritter away. Otherwise, the title of this part comprising three chapters would have been “Future of human well-being and governance”. In the current format of “Future of governance and human well-being” the latter is considered the goal of governance. In the former title human well-being remains separate from governance giving an indication that it is not the prime purpose of governance. Many theories, such as theories of power, come out of this presumption. Further discussions on the topic are a continuation of the purported idea of GBNS. This means the proposed way to achieve human well-being is through GBNS as the sole purpose of governance. It also means the way to human well-being in a human system is through competent, matured and responsible governance by the agents of the people in whatever types they may be. It is national security, when applied to national governance.

If that is acceptable, one should also understand the concept of national security and its process, national governance, technically comes to a halt at the boundaries of the nation, in spite of the element of geostrategic security. It may not reflect even on the global commons unless the interests of the nation are specifically projected and accepted by the global community. The process beyond the border of a nation though expected to be identical with respect to the concept, changes format based on country specificity. This is easy to understand if one can watch the armed forces of each country and how they vary country specifically also differing in performance situationally. Armed forces are uniformly shaped in purpose all over the world, but their nature and functional characteristics are country-specific. The process of governance is relayed over the web of nations moderated and modified by the requirements of each nation. Unlike in a relayed continuous process, the process undergoes country-specific alterations. The process changes accordingly though the outcome expected is the well-being of the citizens of the respective nations, but not that of the global human system as a whole. The indexes of well-being accordingly changes. The nations are not governed collectively as a unitary system with sub-systems, but as exclusive and independent systems. This is where the nations become comparable with respect to the global system in whichever form it exists. The fact is that there is no provision for focused global human well-being in the present scenario of governance. An exclusive global governance system, similar to national governance system, is not likely to be established in the near future, though there are global collective activities under the United Nations’ vintage charter that still holds on to some extent justifying its formation nudging, not replacing, the now fossilised League of Nations. This can be seen in every collective policy and programmes including Agenda 2030 which is critical to align the nations along the track of sustainability. The separation of nations as individual entities is very visible in the Agenda 2030. Every signatory in the UN list is party to it. But they will do it in their way subject to the global format, though. It is not charted to cohesively bind the nations into one world of nations for obvious reasons. It is simply not possible yet to

think of collective global human system as the Santana Hindu² philosophy of yore, "*Vasudhaiva kutumbakam*"³ meaning "Whole world is a family". The crux of global governance towards the total well-being of the human system is hidden in the chant that highlights the principle of *vasudhaiva kutumbakam*.

31.2 Fantasising Reality—"Vasudhaiva Kutumbakam" and Others Similar

A genuine doubt could arise about the term *vasudha* (the world) in the chant *vasudhaiva kutumbakam*. Considering the chant is an extremely hot and time-pickled (around 3000 or more years) idea, though presented in a new bottle here, one has to be careful to link it with the then period that certainly was not what it is now. This is important under the continuum theory. Hence the frame of reference in the analyses of the idea of "whole world is a family" should first seek what is meant by the term *vasudha*, the world or thought by those scholarly people at the time it realised in their intellect. Assuming the exactness of the term is clear. Does it mean the whole Planet or only the locational area to the extent of reach of humans around three thousand or so years back? The slogan *vasudhaiva kutumbakam* in the main chant reverberates, in many cases passionately sans any kind of prejudiced nationalism but pride of being a human in a friendly and harmonious system. There are also other phrases such as *atithi devo bhava* (guest, the visitor, is equivalent to God)⁴ that show compassion and free and matured mind in terms of respect towards other people. For the present-day India, global camaraderie is a part of governance as one can see this verse from *Maha Upanishad* (about 1000B.C.E) inscribed in the entrance hall of the Parliament of India. But the chant remains a desire or a slogan that is not pragmatic and remains as a dead wish or expected but unreal demeanour that could be used as a brand slogan without a product. That also means the reality perception converts it into a new form of intellectual application that is neither real, unreal nor abstract, but a desirable wish in the wish collage⁵ that could be turned to any of the three if it has to be applied pragmatically in an activity whether

²The term Hindu is an exonym probably by the then Persians meaning those living across the Indus (Sindhu) River were called the Sindhus.

³The theme is from *Maha Upanishad* VI.71–73. The date is unknown and originally from *Rigveda* the oldest known Veda of the four vedas considered to be in the later stage of Bronze Age and orally transmitted since the second millennium BCE (around 1500–1200) in ancient Hindu knowledge tradition. *Maha Upanishad* is considered to be the most ancient of Vaishnava Upanishads attached to the last of the four vedas Atharvaveda (1000–900 BCE).

⁴This idealistic thought process brought the nemesis of many host systems subsequently and impacted on ethnic security. It reflects in the present system.

⁵In management the term wish list is used. In sociological behaviour people write their prayers in a chit, or thread or cloth etc., an place in a cauldron, tie to a fence or a tree of fulfilment or to ward off the evil-bad the term used in this study to all these together is desiree model (model of desire) these

governance or not. It is not yet done. But still the whole world consenting to becoming a family in the spirit of it will have to wait till it identifies a common critical threat slithering or growling at the door of humanity one day.

All said scholars consider *vasudhaiva kutumbakam* as one of the all-time admired expressions of historical India that projects ancient Indian intellectual thought process in matters human. The expression affirms it. It calls for a world without discrimination of human systems. While this chant was in Sanskrit, considered to be the second oldest language in the world, there was an equivalent statement in Tamil, taken as the first language in the world, though much later. It was quoted by the Sangam age⁶ Tamil poet Kaniyan Pungundranar⁷—*yathum oore; yavarum kelir*, meaning “Listen all, all places are ours”.⁸ This quote is depicted in the United Nations.⁹ But the case is that the term whether in Sanskrit or Tamil was not slogan for human governance but for individual human to emulate and practice in his or her way of life. It was not aimed at a world under a UN or global parliament. It is also the concept of *Bhagavad Gita*, the eternal Hindu scripture of wisdom for self and other similar treatises that call for understanding others for knowing and understanding self to create a conflict-free world. But the question whether such a state of affairs can be achieved is unanswerable for the fear of going wrong as there is no method that can be identified to test it. The interesting aspect is that the world still talks about “one world and one people” in one way or another through those whose voices matter, though still without result.

The quick conclusion for this study is that such a principle can exist but its expediency is a strict no-no since humans are not designed to live in compassionate mode of assisting the other to live at the cost of self when competition is one of the

are part of the perceived security hamper content. They can be used for governance by transforming or processing them into any of the three forms of ated existence: real, unreal or abstraction.

⁶The Sangam Age was the period of history of ancient Tamil Nadu and Kerala and parts of Sri Lanka spanning from c. sixth century BCE to c. third century CE. It was named after the famous Sangam academies of poets and scholars centred in the city of Madurai. Such was the age of “Sangam Period” which was lived by three great dynasties of Cheras, Cholas and Pandyas. Going by the trend of UPSC questions asked in prelims and mains, it can be assumed that this is an important topic for India’s top administrative examinations.

⁷The word Kaniyan means astrologer who calculates life and its dynamic movements based on date, time and location.

⁸This statement similar to *vasudhaiva kutumbakam* means “we belong to all places and to everyone”. It also brings out an interesting find that human thought process can create original ideas as replicas of similar thoughts at different places at different times and therefore they need not be cited or taken as a copy of the previous ones. There is a time gap between the two thoughts though they are identical in meaning but the thought process were in different languages. They are, in all respects, original thought processes in all arguments. (The author fondly and respectfully remembers his scholarly friend Malayil Subramanian (1944–2019) with whom he had elaborate conversations on human thought processes and how they could be independent of each other in the evolutionary momentum). This also supports the case of unitary civilisation of human system where people develop intellectually in a responsible way even in own niches).

⁹Kaniyan Pungundranar. https://en.wikipedia.org/wiki/Kaniyan_Pungundranar. Accessed 12 July 2019.

limiting forces of survival for any living thing. Humans are not separate from other living beings as evolution is not random but threaded in a chain of continuity. Humans cannot isolate and start afresh as Life2 under different and exclusive principles and governing forces. It is against the laws of survival where maximum value can be gained by containing the human survival emotions becoming destructive to another which can be achieved only through governance and rule of law that requires the former even in crude form. This way governance can be effective for global family in whichever way it can be deliberated for administration. To that extent *vasudhaiva kutumbakam* and all its combinations since the last 3000 years till date are realistic fantasies of wish fulfilment that could be made conditionally practical. Humans can do it but may not be necessary that they attempt it unless there is a common cause. Agenda 2030 originated from the burning concerns of the present-day world (twenty-first century) where the world nations have joined for a commitment identifying the causes that may deny a future to the generations of the present if delayed further. But can the world create a *vasudhaiva kutumbakam* model without a reality situation of grave danger to human existence on the Planet? It is not only considered impossible,¹⁰ but also changed the Chinese mental stasis to consider the Himalayas as a boundary-less expanse (Box 31.1).

Box 31.1: Is *Vasudhaiva Kutumbakam* a Geostrategically Counter Adage Especially for India?

The question whether adages and slogans can unify the human system is less important when it comes to causing separatism under human nature of picking up the negative in even seemingly positive communications. The adage *Vasudhaiva kutumbakam* is considered as the "loftiest Vedantic thought" even in the Indian *puranic* (ancient) literature *Bhagavata purana* (see footnote 11). This adage, according to Chung Tan, influenced the Chinese culture and is an example of "dynamics of boundarylessness of a Himalaya Sphere phenomenon, viz. Chinese culture with Indian input".¹¹

The question is, if a global governance format is not feasible, can this principle be brought in a nation by GBNS, can be answered in this light of appreciation. Yes, very much, though caution needs to be exercised about interpretation by different

¹⁰The *Bhagavata Purana* (500–1000), the Indian *purana* calls the *Vasudhaiva kutumbakam* adage of the *Maha Upanishad*, as the "loftiest Vedantic thought". This adage, according to Chung Tan, influenced the Chinese culture and is an example of "dynamics of boundarylessness of a Himalaya Sphere phenomenon, viz. Chinese culture with Indian input"

¹¹Chung, T. (2015). "Himalaya Calling." *World Scientific*. p.63. https://books.google.co.in/books?id=Gjm6CgAAQBAJ&pg=PA63&redir_esc=y#v=onepage&q&f=false. Accessed 15 October 2019. This will also throw light into the probability of India's open mindedness towards accepting people of every walk of life may have caused its own sufferings of aggressive violence since beginning and still continues in one way or the other. If so this tendency of accepting all by nations under responsibility towards humanity may need to be regulated carefully.

human systems. That is where GBNS becomes a recommended format. It is possible if the primary end objective, the goal of governance, is well-being. It is a condition. It has to start from a nation and grow into global dissemination by practice. Here it is important to note the constraints.

The ideology of the human system is not *vasudhaiva kutumbakam*. It cannot be. Life is different from living. Life is conditional to environment whereas living is a matter of survival under extreme constraints. The laws of living are different from the laws of life. The living thing will survive as long as it is fit. Living for others in a human system can deplete if not deprive the self of the competence to survive. It is hidden in many human activities. The oxygen masks warning to cover oneself before helping another in an aeroplane, the naval war command not to stop the ship to pick up a person fallen overboard, protect self before fire fighting a fire or getting into disaster scene, to simple wearing of masks by the doctor dealing in a pandemic case . . . all indicates that one has to help first to survive and it is against the principle of helping others beyond certain degree. In other words the last man surviving should be self for everybody. This is where live and let live gains new format. Live first to live last is a transformation of the survival of the fittest theory. It is a fantasy concept, a concept that is desired, being fully aware that it is not practical. The world believes in and struggles through “it is only ours, not yours” principle are equally a fantasy that will meet more vehement resistance.

Another Sanskrit term widely used in Indian scriptures and echoes continuously in the halls of Good Samaritan conclaves and advices is *Loka samastha sukhino bhavanthu*.¹² It is a wish in the form of a prayer, of course, aimed at God (who else?), the all powerful, not the government to make everything fine for everybody in the world. “Let all the people in the world feel well”, the chant says. *Loka samastha* can mean people or the world in Sanskrit. But the term *sukhino bhavanthu* is translated as “be happy” the common term of communication. The author doesn’t agree with it as *sukhino* is a term with a larger meaning implied in human “well-being”.

The continuum India has been advocating well-being for the whole world since ancient days of knowledge generation through thought processes. Even today, the policies of India have this desiree expression, though not at all pragmatic at least for a long period into future. Perhaps the genetic infusion of the feeling may be the silent cue in the author to write this charter while explaining GBNS though he knows well that such a utopian world is not possible for the reason that it will lead to the extinction of human systems sans survival competition.

While the above statements and negativism about wishes of continuum India in this charter by the author is only an indication of hypothetical expressions for this study, there are many examples of similar arguments about their impracticality in socio-political circles only to express opposite statements for socio-political reasons. Examples that India’s critics especially within quote to show how the Indian mentality of the three slogans added with the motive of *ahimsa* (non-violence)

¹²Mentioned in the stone inscriptions of the Sangama Dynasty (1336–1485). This is quite recent compared to the previous adages in the common theme of well-being for all without differences.

quoted so far has destroyed India in course of time and today India is still a party that believes in *sabka sath sabka vikas*¹³ though the governments are more careful. They say practising such principles will lead only to defeat and extinction. But, then, India still stands as the world's longest continuum and of course, most violent.¹⁴

Vasudhaiva kutumbakam and similar jointers still lace the speeches and policy covers as catch phrases in many countries. These principles cannot be part of policies because they are fantasy phrases. There are people who believe invincible national strength needs to be acquired first before preaching of supporting others. This also indicates success in national security governance and improved well-being of citizens could be another way when nations can be bound d together through need satisfaction of common governance.

It was Atal Bihari Vajpayee; the prime minister of India quoted the chant *sarve bhavanthu sukhina* in his speech at the much-publicised UN Millennium Summit on 8 September 2000.¹⁵ Expanded, the chant is

"*Sarve bhavanthu sukhinah;
Sarve santu nirmayah;
Sarve bhadrani pasyanthu;
Ma kaschit dukha bhavet*".
"May all live happily; may all enjoy good health; may all see auspiciousness; may none experience distress; and may peace prevail everywhere".

It was reported that leaders of 152 countries heard him in rapt attention.¹⁶ Four years later, it was also stressed by his successor, Manmohan Singh. The underlying principle of his keynote speech in the leadership initiative organised by a leading Indian daily, *Hindustan Times*, in New Delhi, India on 5–6 November 2004, was also India's sustained belief in considering the whole world as a family. He repeated the call for *vasudeiva kutumbakam*. In his address, he stressed the need for cultural coexistence of the people of the world even if there were clashes between nations.¹⁷ Narendra Dharam Das modi, India's prime minister since 2009 repeated it more frequently. This shows there is chance of the chant and similar ones repeating it and coming from India world's most populated country.¹⁸

¹³This means everybody develop together. The genetic root of the thought process can be traced to *vasudhaiva kutumbakam*.

¹⁴The term most violent is a relative expression to the continuum span. Violence and also the good things in a human system will be proportionate to the span of its continuum. Any comparison, therefore, has to be with another of similar continuum span.

¹⁷Nagi, S. and Iyer, N.R. "Nations Clash, Cultures Coexist." *Hindustan Times*, New Delhi. 6 November 2004. p. 1.

¹⁸Though statistically India is second to China in population, it is the author's heuristic conclusion that India will be the most populated on time-based average as well as by census flaws and limitations. This is done by biomodel assessment and superimposition of the comfort zone factor that is India relative to China even if India comes out with new policies of demographic control.

It could be argued that the principle of global security, in its essence, is hidden in these two *Sanskrit* words and the way it was projected by the two leaders, in spite of differing political ideologies, to the representatives of the world communities. The leaders had the wisdom and power. But does a closer look show that these words were merely projections of fantasy? Were they part of wishful thinking that the world normally engages in the face of unacceptable realities? The idea of the whole world as a family, as projected in the ancient scriptures, was at a time when there was no possibility of practicality of the concept. It was a period when the family was an example of jointness. Today, the people, even in India where the idea originated and those outside, who would have been influenced by the ancient cultural traditions of family jointness, are largely deviating from it. Families cease to be the symbols of closeness in spite of their consanguine beginnings; they are riddled with conflicts based on honour and economics. The families are disintegrating and have problems of unequal cultural extensions. Molecular families have become a reality and soon, as the way it is seen, human lives could even become singular. The world is witnessing a new group of people, the asexual humans, never heard before seriously. They are strictly individuals who like to go at it alone. In the time of the quoted scriptures, visualisation of the world was in a constrained space. The size and nature of the world would have been incomprehensible for those who lived and learned from observation and visualisation. They were not connected the way the world is today. So, it was natural that their perception was limited to the surroundings and their characteristics, generally termed as environment, guided by narrow vision and comprehension of the period. The closest they could visualise would have been the human systems around, often involved in conflicts. The example they could find would have been the most formative pattern of a group—the family that was joint for reasons of security and personal needs at that time. So, the idea would not have been scripted aimed at the entire world, but the perceived world or the community around. They also would not have felt the world should look like a paradise. Here, it is important to understand that the aim of national security or global security is neither creating a paradise on earth nor converting the world into a paradise. Anyone who claims it could be made into a paradise or at least a coexisting family, therefore, hints at a wish rather than a pragmatic endeavour. A wish or fantasy has the inherent acceptance of impracticality. Even if it were aimed at objectivity of a concept, the lead would have been towards perceived security and not the basic essentials of apparent security. Fantasy projections and wishful thinking provide the base for building spiritual security as explained in this book—the filler that balances humans in their quest for apparent security and beyond. Even apparent security—the basic essentials the government can provide are much short of actual requirement. The gap between available apparent security and individually perceived security is filled by the essentials of spiritual security. It is the constituent part that balances the human system in a world when hope that attempts to erase uncertainty dissolves in the vagaries of negativism. In spiritual security, the individuals withdraw to themselves. Pragmatism, if any, in such statements may yield to the strong forces of human conditioning of millions of years and will remain a wishful fantasy.

Fantasies are also dreams that the determined can convert into reality. The scientist statesman of India, A.P.J. Abdul Kalam, often spoke about the need to dream to achieve. In his observation, experience and words, ignited minds can transform the dream into reality.¹⁹ Fantasy stops here, at its realms, and pauses before taking a turn into perfection of actuality. It is possible with the power of the mind. The world had witnessed it before. At the same time, the world is conditioned not to deviate seriously from self-centred interests of the individual self. That is the conditioned slogan for survival. This conditioning could be traced back to the day when humans were first beamed down on earth with a dictum to survive and not to perish, without any strong survival mechanism except a small brain tucked into a tiny skull slightly harder than an egg shell, to work it out. Fear is the key for survival and also the effervescent medium of negativism. If global security has to become a reality, then it has to come from the inherent fear of the humans themselves in their own existence. It is a bargain based on the probability of a blend between the insecurity of a primate in the face of a threat and the wisdom that evolution has etched in its psyche.

The idea in the scriptures, however, is not that of misanthropic falsifiers. There is wisdom in such words. When wise people gesticulate with concise words, the ignited minds should get ready for their usage and application. At least the idea of such scriptures should be viewed seriously for their practicality within limitations of the period and intellect. In a nutshell, the scripture *vasudhaiva kutumbakam* invites those who govern to try their hand at global security and warns indirectly about the never-ending quest contained in it. Both establish the possibility of global security when better sense prevails, and also warns about its associated constraints.

In spite of this argument, making a case for global security or at least acceptance of national security, as a worldwide concept for the well-being of the people has to find roots somewhere even if it is a fantasy statement. The quoted statement provides a kind of refuge for it. That is not all; there are many supporting thought processes that are distinctly vivid and outside the barriers of fantasy. The very existence of the United Nations even when doubts are casted on its actual power to influence the nations in global decision-making; the manner the turmoil within and against it is managed under conflicting situations by international community; the statements of the secretaries general and their acceptance by majority of the nations; the principles of collective security and global development; and attempts to review its structure and governing rules are all indicators of the dynamic thought processes in the direction of global security. That is not all; the very process of globalisation and the slow and steady loss of power of national governments in key areas are also symptoms of developments that may set the appropriate trend. There could be more arguments in its favour and against it.

The world was not the way it is today when the scriptures that proclaim its unified outlook were written. It was small, limited to the knowledge the humans had about it. The people knew each other in a very limited space. The world was not crowded.

¹⁹Kalam, A.P.J.A. (2014). *Ignited minds: unleashing the power within India*. Penguin.

Population density was low. But did the people feel safer and more at ease in the past than they feel today? It is not known; it has to be deducted under bias. The world of thousands of years back in history cannot be compared with the advanced world of today. A biomodel deduced from Colin Wilson's *Criminal History of Mankind*²⁰ clearly indicates the world was pretty bad in the past and progressed or rather civilised in course of time. And for all practical purposes, the world is advancing. That means it is better today than it was yesterday. And if a scripture of this sort was written thousands of years back, it should equally or more aptly apply in today's world. The question is, Is the world chasing a chimera inadvertently even today that was first felt in the minds of a few wise people thousands of years back? One has to ask the secretary general of the United Nations for an answer with a feeling.

Undoubtedly, any feeling for considering the whole humanity as one for governance for well-being has to come from the commitment to global security. Global security is not an overnight stopover. It is a process. From the day the scripture was written about the whole world being seen as a family, it took thousands of years for the first international organisation, the League of Nations to come up. But the idea was born and became etched permanently in the psyche of new generations. Though the League of Nations gave up the ghost in the natural way, the idea persisted and took shape in the form of the United Nations. This does not mean one has to believe in the theory of reincarnation or recycling a smoker's pipe into a plumber's duct. In fact the League of Nations was there breathing its last when the UN was born. There are serious asymmetries in both the organisations. The symmetry lies in their basic dictum—based on the demand from the world community to cuddle and huddle together. That was how the ancient primates kept the fire, the most valuable of their resources, burning. The fire also elevated humans from the level of chewing carcass to the level of chewing barbecued carcass (still carcass, though) huddled around engaged in the act of ingestion. From the behaviour patterns of the humans with respect to their needs, a close observer may see signs of global security becoming a gradual possibility, though the shape is not known. There is a caveat that the signs could also be deceptive.

²⁰Wilson, C. (1984). *Criminal history of mankind*. Granada. According to the author, the public conscience in the human system of yesterday started waking up largely as the result of the works of authors like Charles Dickens and Victor Hugo. They touched people's imagination. Till then, death, mayhem, sexual abuse, incest or any kind of amoral life (as it seems to be today) was either acceptable to society or not cared for. Life turned around oneself within a group in a social system. This is in spite of the formation of nation states and the concept of nationalism meant for security for a group. Dickens and Hugo made their readers to put themselves in the place of the unfortunates in the society. It could not be a change in personalities, but an inducement of insecurity that the readers experienced by identifying themselves with the unfortunates. But, it brought social changes that continue today in different aspects. There is a caveat here. There were societies in the world from the very ancient times who believed in ethical ways of life and value systems of good social order. The example here is only to show that in the nation state principle, collective empathy did not have a prominent place since people were engrossed in their own existence. It is still carried forward. Social empathy, however, forms a background for understanding oneself in the position of the miserable victim and thereby prevents a harm being committed in the normal case.

The idea of global security lies largely in the concept of national security focused on the world community. At this moment in time, it is asymmetrical with nation centred security perception, though such a perception contains all the ingredients for the more advanced concept of global security. Within the limitations of this study, one can deduct the path towards its concept, though much wider and seemingly unapproachable in the current context. Therefore, this work attempts only a peek into the concept to understand the hypothesis of global security under conflicting views and observations; some of them may even introduce ostensible contradictions in the statements.

With all these findings in the random search is there a chance for the world heading toward global security? Nay. . . , not for a very long time as human are not made for it. But what is the idea of global security? Before that the reader may pan through the box on India's continuum catch phrases

Box 31.2: India's Continuum Catch Phrases on the Idea of Global Security

The catch phrases are called continuum catch phrases as it is continuing for the last 3000 years or so. It shows India is a long-standing continuum as a human system that has always depended on knowledge more for spiritual security by desires of human well-being and apparent application of the adages for it, but hasn't succeeded much the reasons for which will be in the principal laws of life (see quote), more so nature. The catch phrases are articulated below.

1. *Vasudhaiva kutumbakam (Sanskrit) (Rigveda period)*
Meaning, "The world is one family"
2. *Yathum oore; yavarum kelir, (Tamil) (between sixth century BCE and first century CE)*
Meaning, "We have sense of belonging to every place and everyone is our own"
3. *Loka samastha sukhino bhavanthu (Sanskrit) (1336–1485)*
An invocation meaning, "May everyone, in the whole world, be happy"
4. *Sarve bhavanthu sukhina (Sanskrit)*
A mantra invoking, "Let the entire world be happy"
5. *Sabka sath sabka vikas (Hindi) (2014)*
Meaning "Together with all, development for all"
6. *Sabka sath sabka vikas sabka viswas (Hindi) (2019)*
Meaning "Together with all, development for all, the trust of all"

There are various other *shanti* mantras (recitals on human well-being) in Indian scriptures and ancient literature. All of them are in vogue and repeated on various occasions aimed at "the well-being of global human collective".

31.3 Ideating Global Security

Global security has never been figured in any nation's agenda. It may not come up for a considerable period of time, though there could be enhanced global cooperation on many issues. At the moment it is restricted in the oft-repeated terms of globalisation, de-regularisation, liberalisation, regional and global cooperation, collective security, etc. Barring the partial thought process on the League of Nations, first time in history, collective security issues under a single umbrella were thought about when some of the nations of the world sat down to discuss the possibilities of averting another world war after witnessing the two global wars. It succeeded to the extent that there was no total war of such magnitude since then. It stands in support of the United Nations existence. But the term "United Nations" is an oxymoron. To expect nations with their boundaries and sovereignties, their egos and ambitions, their ideologies and convictions, and their infinite capacity for self-expression to come together to serve the common good of humankind is to chase a chimera. This is especially so when there are so many issues that govern people today with divided ideologies. The organisations of the United Nations could get isolated in a world divided by strong religious conflicts, ethnic choices, power games, etc., in the process. There are many other issues that keep the divide between people permanently. Nationalism is another force, though arguably dwindling. If the UN raises a great deal of cynicism, it is because nations are unable to rise above their national and other dividing interests. Global security, therefore, has to be wrought within these dividing forces for a long time until the national interests merge with global interests. That is when global security principles will emerge.

The identity of the UN provides it an attitude to strive for global security. Its main task will be to control the dividing forces, which are perceived psychological necessities, but create conflict and strife among people. Gradually and slowly, the world is becoming aware that there are threats to global security that can surpass all other efforts to contain them within a nation's boundary: natural disasters, ecological degradation, pandemics, ethnic divide, transnational crimes, terrorism, militant activism, etc. In addition, pressures exerted by probably and understandably the most powerful driving force in the living world—the power of economics, pulls people in different directions under nationalistic concepts. They have now experienced the economics of globalism, though there are many who are sceptical about it. Still it is not the time to predict whether globalism will replace nationalism in the better interests of humankind. Among dividing forces, religious fanaticism and ethnic separatism are the strongest and deep-rooted emotions in human psyche that may frustrate the efforts of globalism to take root for centuries to come.

Biomodelling the concept of national security through the changing family concepts, existing world standards of nations and behaviours of other organisations including family businesses shows the trend towards disintegration. The number of nation states is increasing, families are breaking down and family businesses are splitting apart. These are human systems. The average overall dimensions of human systems such as families, corporate houses, etc., are decreasing and their numbers are

increasing. The tendency for nation states is not to enlarge or macronise by integration or merger, but to micronise into smaller units. The forces that keep a nation together are induced and not inherent in them. Keeping their nations together from breaking away has become a major task for many governments. National security may play a leading role in amalgamating nations or forming a union. Without induced forces, human systems show difficulties in sustaining their integrated state. On the other hand, there seems to be certain identity of mind with respect to international organisations, elimination of world wars, international support in calamities, international agreements, globalisation of economy, distrust in the intentions of the superstate, etc. Governmental powers are weakening under such pressures. While the former, the disintegration of human systems, means that the world will never be united, the latter, integration of systems beyond nation states, is an indicator that there could be a counter flow towards national security. What is required to be seen is the resultant trend. The time is not yet ripe to analyse the resultant trend of the flow. Such trends are requirement based and not exactly jointness of acculturation towards a common share in life's capabilities. Added to this is the hierarchical order of nations in their economic behaviour. Even if the entire world unites, the tussle for superpower status and subsequently its dominance to keep the world at its feet for its own survival cannot be ruled out under normal circumstances. The chimera, in the shape of a wishful fantasy, clearly hangs around; at the same time, the quest of the seemingly impossible is also quite interesting. Though the concept of global security under these circumstances is highly improbable, chasing a twisted shadow keeps the human process alive and active.

31.4 Unifying World

There are many collective activities in the world where nations and their citizens participate. But so far there was no world unity day propagating the well-being of global citizens. That also throws light to the fact that global community cannot be viewed as a definable system. Many nations organise national unity days on different dates annually under country-specific objectives. The fact that the unity days are celebrated differently by nations also mean the chances of their continuity in future cannot be assured. Even if it continues the dates can change as per the whims of the governments. But the unifying theme of unity days all over, where celebrated, is that there is a kind of consensus and awareness that the people of a nation should remain unified for the well-being of its people through governance. But it is not so for the global humans as a whole. That is fine. It is just an observation.

There are many conventionally organised unity days across the world depicting various ethnic segments based on belief systems, languages, demographic affairs (e.g. refugees) and so on. India celebrates the National Unity Day (*Rashtriya Ekta Diwas*) on 31 October. But a consensual Global Unity Day (GUD) with the participation of all countries and other entities are yet to come up among the world collectives. It also means the idea of a unified world and global security is a far cry as

nations themselves are yet to settle down. This is evident from the way the nations celebrate their unity days in general. There will always be segments that may keep away from the unity day functions. Many other celebrations are given much more importance than unity day celebrations. Evidence is in the convergence of international organisations to celebrate world unity days or weeks under various themes. Many civil society global organisations and initiatives come together in alliances to declare world unity weeks with various activities. One such celebration is based on the day of signing the UN Charter. It has been mentioned that the UN is not the world and with the limitations that the UN faces in its charter and authority there is a long way to go for a unified global system that will make the people feel the whole planet belongs to them. The UN is aware, and along with them the world leaders and present-day positive illuminaties²¹ feel the world should be a unified system for wholesome well-being of people. But it is not going to happen as the constraints are far too many. Probably they are required to balance the system itself. The global community is aware of the deep divisions, inequities and conflicts that fracture and fragmentise human systems today. But they are different from the past. It shows relative to the past the world is more humane.

31.5 Twenty-first Century UN

Kofi Annan (1938–2018), the then Secretary General of the United Nations (1997–2006) was instrumental for the Millennium Summit at the UN. Leading personalities belonging to 12 prominent world religious faiths gathered at the United Nations for the first time between 30 August and 2 September 2000. They discussed global peace and security. It was an extraordinary congregation for a purpose with a vision of human coexistence in the troubled world. Their aim was to sign an ambitious document titled “Commitment to Global Peace”, which emphatically stated, “all religions were equal” and so were men and women. This statement unequivocally condemned violence committed in the name of religion. They led of exposition of various themes in a novel way for peace on earth. This however does not lead to ultimate global security, but is meant to thaw the differences between people of various religions for better understanding and non-violent behaviour. The advantage of the UN experiment is to bring in the much-needed value system in human understanding and behaviour.

The issues discussed in the Millennium Summit were not contained to religion alone; it covered various issues related to conflict transformation, forgiveness and reconciliation, global challenges and local initiatives, tolerance and poverty. Religious leaders see religion in different ways. A close observation of the religions of

²¹ Positive illuminaties are those who are not in direct governance as government personnel but have the power, authority and the will to lead the world directly or indirectly to positive outcome. Negative illuminaties are the people with similar capacity but act as anteforce.

the world shows that they have various aspects: symbols, practices, rituals, rules, values and origin at a particular time of evolution of humankind. While the first and foremost religion in the Christian era of the world united a group of people with an underlying organised common faith 21 centuries ago, the last of the major religions, Sikhism, was originated in India in 500 AD.²² There were no major religions since then. It was only expansionism of the existing religions with their classic tenets in flux through stormy periods from age to age through fragmented ideologies and divisions within by alternated faith. Every religion had turbulence from within. And each one of them withstood the turbulence. While religion loves diversity according to certain believers and leaders, it is the commonality of the religion that is important when one has to see the security aims through religion. The commonalties are the perception of God, godlessness and values associated with the belief systems. Where there is no religion, the culture stands in. Assuming that religion is one of the ways to seek life, the focus of perception, the only way one can stem tolerance in the world is to inculcate and foster human values and instil a yearning to learn about other religions including cultural religions. All religions preach the same is a point here; and you understand one, you understand all is another argument, though externally religions may look different. Under such arguments, the oft-repeated advocacy of wise people in learning about other religions means understanding the reality that all religions preach the same—concern for humans. It is obvious, looking at the reasons and ways religions were formed in the world that they all should preach the same under different packages. It is true even for those that do not commit to the existence of God. The period of formation of religions was turbulent for security and evolving human needs. Under such conditions there was the need for people to slip more into the intense spiritual security offered by religions.

One tends to forget that the purpose of the UN is to provide global collective (apparent) security, as defined by it in the Charter, by international governance. Seeking the support of agents of spiritual security related to religion was a deviation. However, the UN is within the rules if the impact of spiritual security entities to collective security governance is what it is concerned about, not beyond that. For any system of governance, it is better to live it that way. However, the impact of the Summit is yet to be seen in the world that continues to be riddled with problems. The summit does not seem to have caused any impact except establishing the thought process. That, however, is an achievement for the secretary general and those involved in the vision as the process is being pursued further within the framework of the United Nations. The results were never seen in the positive as the subsequent

²²In this work what is considered as a religion is the organisation of human systems under a perceiver in the name of a God or no God principle that started before Christianity with Zoroastrianism (seventh century BC), Jainism (seventh–fifth century BC), and Buddhism (sixth century BC). Christianity was followed by Islam (seventh century AD) and Sikhism (fifteenth century AD). (Dates from *Encyclopaedia Britannica, Ultimate Reference Suite, CD-ROM, 2004*). The rest of the people belong to cultural societies as unconverted original people according to this work where their culture substitutes for religion with identified gods or no gods, the focus of perception, which is essential for spiritual security.

events proved. The terrorist strike on the United States on 11 September 2001 was an example. It was direct power projection of the anti-force to governmental systems. Another issue about religion and global security is that it is not religion alone that keeps the world diversely disunited. There are other causes too, some of them are too intricate to dissect and examine. Perhaps, the world under fear has demonised religious beliefs in such an aggressive manner that more intricate problems to global security are able to manoeuvre freely and unnoticed. The world needs a vision to see the problems beyond the hype and hoopla of imagined abnormalities in the matters of religion.

31.6 UN and Ambivalent World

In the midst of an ambivalent world, it is the United Nations that stands alone as a sanguine metaphor of hope for the world community. The UN is relentlessly following the outcome of the Millennium Summit past the obstacles. Kofi Annan's attention to the aspirations of the world community set out in the Charter to provide collective security to all was never waning in spite of setbacks. A High-level Panel²³ was constituted by the secretary general to assess the threats to international peace and security since it was felt that there were deep divisions among member states on the nature of threats faced by the world that called for appropriate use of forces to make the organisation more effective in handling them.²⁴ The Panel, headed by Anand Panyarachun, former prime minister of Thailand, with eminent and experienced personalities from various parts of the world as members was also tasked to evaluate what the existing policies and institutions had done in addressing those threats, and to submit recommendations to make the UN more effective so that it could provide collective security for all in the twenty-first century. It was an ambitious task.

The report, titled, "*A More Secure World: Our Shared Responsibility*" called for a broader, more comprehensive concept of collective security. The report argued that capable and competent states must be at the forefront for proactive action in combating the identified threats. Their report suggested development as the indispensable foundation of collective security in the modern world. The report mentioned about biological security and expressed concern over it. Basically it meant health security and the need for prevention and control of pandemics like HIV and AIDS. The emerging threats and controlling them by the existing tools—mediation and sanctions—were examined and recommended criteria for use of force.

²³The United Nations' created the 'High-level Panel on Threats, Challenges and Change' IN 2003. The purpose was to analyse threats and challenges to international peace and security, and to recommend action. http://www.un.org/en/ga/search/view_doc.asp. Accessed 16 August 2010.

²⁴The United Nations, General Assembly, Fifty-ninth Session, Agenda item 55, Note from the Secretary General, A/59/565, 2 December 2004.

The panel identified the failures of the United Nations in handling issues related to the health of the world as well as handling the threat of terrorism. The UN does not have an articulated strategy on terrorism.²⁵ It was handicapped in stating a counter-terrorism strategy in the absence of a *consensus ad idem* on its definition among the member states and its intention to follow the rule of law and universal observance of human rights in handling it. Another area of concern was the absence of an articulated division for the nuclear proliferation regime. The Panel warned about the risk of proliferation in future. The report contained recommendations on the issue that ranged from additional protocols, incentives and moratoriums.

The recommendations included changes in the major organs of the UN as a vision for the twenty-first century. This was more with concern on the Security Council membership. Peacebuilding, an affair the UN is serious about, was further emphasised in the report. It recommended a new commission for it as an intergovernmental body aimed at post-conflict peacebuilding. Another change recommended is revamping the human rights commission. Minor changes basically to strengthen the Secretariat for improving its effectiveness for such a serious world forum with competent people was also felt needed by the Panel.

The Secretary General commended the report and expected it would give a boost to the UN's efforts towards collective security principles of its charter with the support of the member states. It has to be seen in the coming years how the report affects the functioning of the UN and its principles of collective security in the world certain to be uncertain.

There were different viewpoints on the effectiveness of the prescribed reforms subsequently. The main issue according to the author is the presumption of UN administration that the nations in the collective knot especially the important ones who can do something will have a common will. The world is yet to get out of its acquired inertia of the past in the so-called Cold War and hyperpolarity aimed at mutual destruction rather than mutual support for a better world. It takes time. In other words the natural frequency of the world in relation to human systems and the artificial frequency of the panel objectives were not in mutual synchronisation to bring radical changes. It means the panel findings can be attempted but may have to be suitably amended and reengineered in course of time observing the reflections carefully. For example, the MDGs, SDGs and similar agendas of universal and unifying developments may be treated as the extension of the High-level Agenda rather than abrupt programmes on termination of the previous. That will be in tandem with the evolutionary changes in human systems especially at geontology levels. The High-level Agenda thereby should not be seen in isolation. Another point is that UN being a collective centre of refuge for the global system, the big marble, should focus on seizing the opportunities as and well they come up. It is not possible to create opportunities in a human environment as easily as seizing them.

31.7 Global Security—Concept and Demand

It is often said that the world after many centuries of war and sufferings is a close-knit community. It is called the global village. Those who argue its existence often quote that nationalism is on its way out and people want to be globally united to overcome the miseries of life. They even argue that in the past the world was torn apart by nationalistic leaders. Strong sentiments of nationalism lead to self-destructive thoughts and power maximisation attitudes among leaders and nations. The twenty-first century began with a war in Iraq (2003), which the invading coalition forces under the US preferred to call a pre-emptive war. The initial phase of the war ended with the humiliation and incarceration of the president of Iraq. His family members were identified, trailed and assassinated as war casualties. It did not stop there. The cost of occupation and subsequent conflicts was US\$228 million per day to the United States according to reports.²⁶ The winds of change blew over the feeling that nationalism and overstressing the requirements of citizens will never bring the world to the proverbial peace. In the second phase, the world witnessed a process of election to choose an agent to govern in the still bleeding Iraq. But the United States has not been able to validate the attack on allegations raised earlier—support to terrorism and build up of weapons of mass destruction. The attack also failed to send a warning signal to other nations seriously. The Iraqis stood divided, this time within an elected agent. In the overall game plan, the attack was a relief for many Iraqis and victory for the United States on its power projection, while a blow to the United Nations and those who opposed it. But the idea of global security was temporarily snatched away by the forces. The idea remains, even if in a different garb, within the precincts of the Iraqi incident.

Nationalism is associated with patriotism that often takes it to an ugly hue. Samuel Johnson (1709–1784), the British writer and lexicographer had said, “Patriotism is the last refuge of scoundrels”.²⁷ How valid is this eighteenth-century statement in today’s contest? Certainly patriots are not scoundrels. The scoundrels do not have to masquerade under the garb of patriotism. There are many other avenues where they can vent the pressures more easily and ruthlessly. No one takes a long winding tour to reach a place faster. Patriotism is one such detour for a scoundrel who should be stupid enough to take it. Those who argue for globalism advise that people should not identify themselves with certain country, culture or religion. It is simple to state, but humans are just not made that way. The Declaration of Independence of the United States, established more than three centuries ago (4 July 1776), states, “*We hold these truths to be self-evident, that all men are created equal, that they are endowed by their Creator with certain unalienable rights, that among these are life, liberty and the pursuit of happiness*”.²⁸ Well, these

²⁶“Stingy Uncle Sam?’ *The Times of India*, New Delhi. 31 December 2004. p. 1.

²⁷Chandra, A. “Look Far Beyond the Nation State.” *The Times of India*, Mumbai. 3 January 2005, p. 9.

²⁸Ibid.

are ambiguously abstract statements, though in the most venerable way, in the most honourable document that a nation possesses—the Constitution. Pursuit of happiness within the combined needs of existence is chasing a condition that is very abstract. Why should one drag the Creator into a constitution? Is it to blame for the failures or share responsibility of the burden of governance? There are authors who say that the world is torn apart from many points of view based on nationalism, religion, culture, ethnicity, selfishness, envy, anger, pride and so on. For the sake of convenience one could include even the seven sins including gluttony. The decline and fall of empires were conspicuous with copulating food orgies. But the deadly sins listed by Pope Gregory have undergone a facelift.²⁹ The world no more considers some of them as deadly sins any more.³⁰

The proclamation of the ancient seers, the whole world a family, is a dream impossible. In reality, one dreams about something that one is not able to gather. The proof is embedded in this statement. If global security is a dream, then it does not exist. Dreaming could be a way of wishing for it. Reality in action is based on demand and the strength of it. A closer look shows a clear absence of demand for the concept of global security. Nations fear others who are more powerful than them. The powerful do not want others to be equal. Even for those who are subjugated, global security in a unified manner is not considered a solution. Nations prefer support from someone bigger than the big fish they are feared of. Within these situations, there is not likely to be a demand for global security. Till then, global security as a product is unlikely to appear in the market.

The concept of global security will have its beginning in the principles of national security. Though, strictly not an extension of national security, global security principles will draw much from the elements of national security. Every element will be amplified in the global security perspective on a broader canvass. Some of the elements may enhance their importance while some may diminish in their outlook and process. Almost all the elements will have a demanding and expanding role in global security. Health security is a prime element. The term biological security explained in the report of the High-level Panel of the UN does not indicate the exclusiveness of health security as an element. The term biological security mentioned in the report of the High-level Panel is a misnomer if its projection is towards health sciences, because the term depicts life sciences that are different, though includes health aspects. It may do better if the UN specifies it as health security separately and not as biological security, which is a larger term in perception and not a qualified element of national security.

²⁹ 'The New Deadly Sins.' *Hindustan Times*, New Delhi. 9 February 2005.p. 21. A word of caution, here. The seven deadly sins, listed by Pope Gregory the Great in the sixth century have been lust, sloth, anger, gluttony, pride, envy and greed. They are currently revamped to reflect the modern age vices. The BBC compiled the new list after a survey that had identified cruelty, adultery, bigotry, dishonesty, hypocrisy, greed and selfishness as the seven new deadly sins. The author is not sure about the views of Pope Gregory, but certainly it shows the way the human world and the feeling of guilt is changing—the changing demands for spiritual security reflects in such findings.

³⁰ *Ibid.*

Disaster security is another element that will have serious impact on global security and so are many others that need to be studied for the exactitude of interactive and individual geometry, different from the perspective of national security. To that extend the approach of the Panel in assessing the UN requirement for the twenty-first century was conventional. There are many such reports that the UN may see in future, each leaving its own marks on the development of the organisation. Each of these marks will be a small step towards global security and its evolution. The continuation of the UN, unlike the League of Nations, is more or less a guaranteed affair. That is the good news for global security proponents.

Among other factors, demand for global security may come from common threats. These threats are primarily terrorism, disasters, concerns of environment, food and health that have cross-border impacts. There could be variations from what the UN Panel has found as threats to the emerging world. It was a different perspective. Here the security issue is not related to the existence of the United Nations, but that of the nation states. When the threats overflow that of the nation states, they, anyway, cannot exist except in the most original form of existence—as a cohesive group with a purpose. It is that group that will indicate the promises of global security. The nation states may or may not exist in the game plan. The choice in front of the world will be to remain united externally or internally to the principles of national security.

Within these arguments and counter-arguments, the concept of global security remains engorged more or less on the same principles of national security, perhaps in a collective sense. The divisive forces that appear obscene are not induced, but imbibed in the human system which are difficult to contain at the global level but could be managed within a nation state by rule of law and effective governance. This means the importance of government. A global governing system under unified governance cannot be visualised at least at this stage of human development. Therefore, the concept of global security will have to evolve in course of time and its definition as well as functions will remain with respect to the stages of human development. Currently and in the near-visible future, the concept of global security will remain within the economic and market globalisation and international agreements to combat natural threats and cooperate for common causes, wherever identified. Not to say that such actions will have an impact on national security governance, though will slowly erode the powers of national governments. Here the original concept, identified in the book, that it is the king (the government) who is accountable for national security will take an uncomfortable beating. Situations will change. The global security and national security will move along an inverse sliding scale. The more the global, the less will be the national. The national governments will lose power proportionately. There are two choices to the governments—allow the powers to erode without losing control, or find ways of retaining control even at the advent of global security and release it in a regulated manner. These experiments are yet to come by and that too will not be appropriate to expect a common procedure for all nations. Each nation will experiment with their policies of governance in this regard. That is one of the reasons the superstate is in a dilemma to handle global security and prefers to take on the subject without the United Nations. The superstate

also has the fixation of world domination for its survival. What the world will ultimately see will be the resultant interplay of such conflicting governances.

Under the unilaterally empowered state, the role of the superstate in global security depends entirely on its choice. The question that may face the superstate in its path will be domination or proactive leadership. The majority change in the functioning of the UN will come from the influence the superstate has on it more than directly from events in the world. Currently, the superstate's policy, as can be seen, is domination in the guise of leadership, because it believes that way it can remain on top. Soon, in course of time, this belief system of the superstate could become a vintage idea.

The concept of global security, if follows the pattern of national security as envisaged in this book, will have its constituent elements. It will be interesting to note that these elements may not undergo any serious change except that they will become ideologically "internalised". The transformation can be visualised hypothetically.

The element of military security in a global scenario will be an internalised problem where the world military forces will be used to contain a rogue militancy or insurgency equivalent in a global set up. Agents of militancy will be ill equipped from the point of view of weapon stockpiles, because serious regulations will affect weapons being trafficked internally. This condition will be in the forefront of denial of global security principles, because in a world where arms sale is perhaps the biggest business, such a situation is not likely to be accepted. Arms business thrives on war, militancy and internal feud and crimes. Any control on arms business is not likely to work. The concept of global security can seriously affect the business.

The element of economic security has a serious stake in promoting global security as globalisation slowly erodes governmental control in states' economic affairs. Environmental security will undergo major breakthrough, since nations will be responsible for it under a global regime. International control over climate change and global environmental aspects will be further strengthened. Resource and energy security will be a matter of sharing and again available for global partnership. The gap between the haves and the have-nots will increase in all these gambits. Elements of health security, disaster security and food security will find better ways of management and more serious global partnership under global security regimes. Demographic security and ethnic security may find issues serious that will not be acceptable for a global regime raising objections from many states. It is even seen in the formation of union of nations where membership is denied on demographic and ethnic basis, in some cases externally attributed to corruption or religious bias.³¹

These elements, therefore, do not support the global concept. Border security will remain, as the way it is internal to a state and under the current scenario where a large

³¹Marinas, R. "Romania Can Join EU in 2007 if Reforms Go On." *The Asian Age*, New Delhi. 22 June 2004, p. 7. The report states that Romania can join the European Union in 2007 provided corruption is stopped and judicial reforms are in place. The rule of law can be undermined by corruption. Bulgaria and Romania missed the first eastward expansion in May 2004.

number of nations have border disputes with their neighbours. The way the wind will blow cannot be determined without serious research and modelling. Geostrategic security will merge with internal cooperation and understanding as in the case of the union of states. The remaining three elements—information, cyber and genome—are anyway international and will not undergo major transformation except that their interaction will be worldwide and with superior benefits.

The above projections are strictly hypothetical and made for understanding the interplay of forces at the elemental level itself. Some favour; some do not. The constraints are also beyond the elements. All these will impede the idea of global security for years to come.

31.8 Summation

The world could never be expected to become a unified potpourri of nation states, for a very long time, because alienation by mistrust and fear within is extremely strong. The chances are that the nations may further break up and part rather than merge or amalgamate into larger unified states. Unifications, if any, will be primarily in economic and military security interests keeping the identity of states internationally. Such unification may part ways at a convenient time. In spite of retaining their individual identity, nation states will certainly need an umbrella regime that could make them huddle against common problems. Such problems are many and there is already a redeeming parasol in the charter of the UN, if followed correctly. The UN, unlike, the League of Nations, is not seemingly deteriorating as the latest events show.

On the other hand, the world is fast advancing compared to the past. The leaders of the world today are more than leaders, and behave differently that may give vent to a feeling among observers that those in the past were giants. It cannot be true because the leaders today are better at governance, which is a more advanced stage of the leadership requirements of the past and hence not individually identified beyond certain limits unlike in the past. Besides, in a situational approach, leadership also depends upon parameters that govern and modify each interaction. Positive examples of such leaderships are reflected and echoed in the decisions of leaders of many nations in modern times (Box 31.3).

Box 31.3: Times Have Moved and So Are the Leaders and Their Achievements in Anonymity

Without quoting names the author finds a lot of leaders providing exemplary leadership and acuity of governance in the crowded and ever boiling world of the day by their superior and daring decisions that many in the past or among the present wouldn't dare. A few examples can be quoted from among those

(continued)

Box 31.3 (continued)

who demolished the terrorist power projection of 11 September 2001 forever (GW Bush), controlled energy security when many national governments were embroiled in it (Putin), brought every nation to the doorstep of United Nations against the flash point of senseless wars in spite of its inherent weaknesses (Kofi Annan), dared to introduce monetary reforms that other nations were only dreaming about (Modi), contained pandemic induced perplexity under absolute discipline in spite of chaos (Modi), resolved issues of a garroted generation (Modi), smothered violent clashes and show offs against the system (Xi), rolled back regulations (Trump), stood firm like a wall against an unwanted wall using the power of the legislative branch to hold the most powerful person on the Planet on check (Nancy Pelosi), projected compassion, tolerance and resolve (Jacinda Ardern), introduced the right seriousness on terrorists (Emmanuel Macron). . .

Modern leaders may not be remembered like an Eisenhower,³² a Khrushchev³³ or a Dag Hammarskjöld³⁴ who could project their charisma³⁵ and situational leniency compared to the present-day world to achieve epitaphs in larger fonts in history. The leaders of the current day world have to deal with much-complicated and “never tried out before” kind of situations where charisma alone cannot resolve the issues in the glaring lights and boom mikes of the media of all sorts. Their lives and deeds are much more transparent and are examined threadbare under today’s information and knowledge world where individual privacy is at a premium. Today’s leaders have to withstand much more stress than their predecessors who survived on charisma in the copious space of privacy. Some of the leaders of the past known for their entrancing escapades in sowing wild oats and indulging in vulgar orgies of luxury may not survive long in their jobs in today’s world. They became heroes because the period

³²Dwight D. Eisenhower (1890–1969). The 34th president of the United States of America. Twice elected.

³³Nikita S. Khrushchev (1894–1971). First secretary of the Communist Party of the Soviet Union and premier of the Soviet Union whose policy of de-Stalinisation had widespread repercussions throughout the communist world. He has been largely regarded as a historical bridge from Stalin to Gorbachev of the Soviet era.

³⁴Dag Hammarskjöld (1905–1961), Swedish economist and statesman who was very popular as the secretary general of the United Nations from 1953 to 1961. He died in an air crash on 18 September 1961 that some analysts consider mysterious. He was awarded the Nobel peace prize posthumously.

³⁵Charisma is a personality trait that can be used to influence “followers.” The trait is attributed to the considered individual human and is strictly relative to the time and period, and the personalities of people around the individual in the system. Charisma is not all pervading as people keep advancing generation after generation better than their predecessors in genetic evolution. This study strictly follows this theory that the young is more advanced than the old along with the another two: 1) women are superior to men by design and 2) the old has seen and experienced more than the young since both have the same time span in a unit of time. It simply means every human deserves respect from the other.

they lived in was conducive for their charismatic blogs of fame. The demand today on a leader is more for executive acuity than plain leadership traits. Their activities will outlast their names. Today's leaders handle much more complicated issues with more discernment appropriate to an empowered generation than the leaders of the past whose charismatic appeals were more legendary than researched or informed actuality. Tomorrow's leaders are expected to play further on the edge at comparative ease. Leaders are not endangered species. They are people of special genre whose capabilities are fast advancing. Situations demand them and situations create them. Situations become more demanding when the world evolves. Under the situation approach, tomorrow's leadership is expected to be much more advanced than what it is today. Such leaderships with wisdom of the present filtered from the past shows promises of a world that will continue to emerge from the past in a better way. It is not optimism. It is the meaning of evolution in a knowledge world.

The need to understand the concept of global security originates from this scenario that the world is moving ahead in a better way compared to the past, slowly but in the natural frequency of the system. The concept of global security flows along with it. The responsibility of the world is to watch it evolving and steer accordingly toward empowered national security, at least in the initial stages of its evolution that is yet to start. If not steered, the evolution will be exposed to chance and thereby uncertainty.

The sweeping changes recommended by the UN High-level Panel on 30 November 2004 recommending the overhaul of its top decision-making group, the Security Council and holding out legitimacy that it could grant pre-emptive strikes by the military, came out at a time when it felt ill-equipped to meet the challenges of the modern world represented by terrorism, failed states, nuclear proliferation, poverty, violence, etc. Even these proposals have serious limitations in guaranteeing collective security since the recommendations are organisation centred and not world centred. Any effect on the world by changing the UN will be collateral, if not incidental. Changing the world should start with the focus on world and not the UN, which is a world body. The aim of the recommendations of the panel is to shape the UN for its existence and not directly the world. Achievements of the shaped up UN in global security will be a byproduct. In this case, the global security appreciation is conditional. Global security is not shaping up the UN to do its job better, but making the people of the world understand the need to remain united at least against common threats. The threats are far too many. The UN may be able to contribute towards it. It is important for the UN to know that its charter speaks about collective security and not collective global security. The original beginning is hidden in the statement of collective security—opposing an invasion collectively. It means physical security or rather military security for the weak. It has to be termed collective global security—a mega term for the concept of national security with modified interactive elements in it. Leadership is important to achieve the concept. It may not come from the United Nations, but the possibility is there for the superstate to engage in constructive global security provided it changes its perception of survival. Such changes in the psyche and character of a superstate cannot be

expected that easily under the current scenario and law of invariance. The world may have to wait.

Superpower is a term assigned to a dominant and powerful nation that has the highest bargaining power in the world including the ability for coercive influence. A union of the world nations under such situation is improbable. But superpower concept could be modified if the nation thus titled understands its responsibilities by virtue of being a superpower and if anything, not an unduly dominant nation. It is also not a power broker, but a power facilitator. It should use its power to influence the world towards the national security of nation states without a partisan approach and build the way to global security. That will bring the title of the last and permanent superpower status to that nation. It can provide security and absolute support to the United Nations as a facilitator of well-being to the nations of the world. It happens when the superpower becomes a superstate in the informal hierarchy of nations. In this book, it is assumed that a superpower once climbs to the top can transform into a superstate. The United States has reached there but it can slip under the power of the axes. . . .

Law of invariance will show the future will be the past. The global system will not change overnight. The catalytic event can only be a meteorite hit, global disaster incidents, or calamities such as barbarian invasions that ended the pharaohs. There are chances for all and more. Otherwise, the progress will be at a pace that will be decided by the natural frequency of evolution, which is clearly seeable in the past.

In spite of adages and motivational slogans from people who matter or mattered at one time since yore, the world is yet to witness any kind of convergence about the idea of a unified human system where care and concern for others is a culture of living. It is still the wild world that refuses any kind of compromise whether within or external to a nation. The nations therefore are the only central systems that can ensure rule of law through direct governance. International law has serious limitations in creating a unified approach in the absence of a system boundary for the global concept. Therefore global governance has to restrict well-being through collectivism and willingness to support. It is not likely to happen conscientiously for a long time in the future primarily because the present-day binary system of power distribution between politics and belief systems cannot compromise the power balance. But there are many like-minded nations with their own anteforces who oppose the idea of human system harmony. But the like-minded human systems can be used by the global collective security system, capable leaders and other responsible motivators and above all the national governments to uphold the principles of individual rights and liberties, and shared values and norms or coming together in the name of future generations through good governance. It means creating partnerships for enhanced communication, knowledge dissemination, cooperation and coordination for shared national security challenges aimed at human well-being beyond the boundaries of nation.

Till then the ideated concept of national security may find its place in national governance with a view into the world nullifying insularism and arrested human systems.

Chapter 32

Will Sapiens End? Premising Governance. . .

Sapiens will hang on; so premise and strategise governance accordingly. . .

32.1 Introduction

At the end of it all, it is all about the end itself. Neural intellect,¹ as a survival tool, that too the highest available and upgraded human benefaction of continuity in the living world today, is only accessible to the “present” *Homo sapiens*.² The limiting lines of human intellect are quite spiky lest humans should attempt a Babel, this time not as an abstraction.³ Human growth and evolution are subject to limitations that, perhaps, act as safety barriers by default to avoid extinction by dangerous cross over. The intellect itself is a puzzle to fathom in depth for humans. Intellect being a survival tool for them, understanding it to the fullest extent academically is not, perhaps, in the package. Intellect has to be understood using the same intellect—a bit of Catch 22 paradox here (Chap. 30). Simply stated, though heuristic in approach, there seems to be a limitation by default that humans should never be able to understand their intellect to the fullest extent, even if they desire to know, for reasons that it may cause their own end. On one hand, humans should die to balance life; on the other, humans should live, to carry on with life. Look deep. Both statements mean the same thing. Life should go on with humans at the intellectual end. This is a hypothetical deduction. The same statement can be reframed more appropriately and truthfully that humans survive because their intelligence is limited to the minimum necessary in support of it. If so, this statement also confirms that intelligence for humans is their survival tool and humans will be able to survive if they put it to use. If that is so and also supported by various *a priori* and deductive evidences, humans are designed not to end, but to transform remaining within the genus of the life form.

People are puzzled with too many questions about the end of the world even before it got into the gear *ab initio*. It is there in the ancient scriptures as anxiety

¹Various neurological factors are partly responsible for the variation of intelligent behavior among or between living things. The neural basis of human intelligence is the benchmark in many studies on neural intelligence. The studies on the subject of neuroscience have been able to identify aspects of intelligence within the neural system of living things and its functioning. In spite of the vast available knowledge, much more studies are needed to understand intelligence among and between species, especially human. The neural basis of intelligence is not only confined to human studies but also to primates, cetaceans and rodents.

²But the *Homo sapiens* should know that intelligence is not human monopoly. It is there in every life form with programmed neural system spread, but in humans it is maximum developed as a competitive survival tool. A raven crow can recognize a water tap and may open the tap if it has the strength to turn the handle with its beak. Intelligence took time in evolution to reach humans as a survival tool. One of the reasons to say that the process of evolution into transformation to another species by branching out from humans may not happen unless there are other survival tools superior to human intelligence, which is unlikely to appreciate under the limitations in the present. This is a kind of falsibility inducement in research appreciation

³The term attempting a Babel is about humans behaving as explained in the Jewish Testament about the Tower of Babel. In actuality Tower of Babel, the myth is a wisecrack on human communication about the use of different languages. The expression here “attempt (doing) a Babel” means jumping over the hedge under overconfidence or impatience to follow the natural frequency of evolution. But the author does not believe that God cursed about understanding different languages but the same language. More specifically, semantic dissonance. (see Chap. 1)

models. It originated first from the anxiety of survival induced by absolute insecurity. Slowly, it turned out to be an intellectual quest put philosophically as well as scientifically to self and in groups. This question reflects all around in the passage of time from early human to the present day sapiens. (Yes, sir, ma'am; the author is selling the idea of sapiens to change the *Homo sapiens* for the better, at least in their thought process, by telling them sapiens are more intellectually forward and more confident than *Homo sapiens*. There is also truth in it. But in this game, the author feels that if the *Homo sapiens* took a step forward mentally and, thereby, intellectually to consider themselves better and more advanced than those in the past, it will make them behave with a bit more compassion with the fellow human beings. And, what should be the date to transform? The author considers 2021 as appropriate for various reasons. And thereafter any moment as acceptable to the individual subjects. They have to decide.

The span of sapiens is important for strategising national security. The continuum of a plan is important under the continuum principle. This topic is about nations and how to govern them with the sole objective of human well-being. So the governments should know will the humans last, if so, for how long? In other words, how long governments and governance will continue? Identifying the span or the time period of a plan is a crucial challenge. Humans do it in a family, the biomodel for every other definable and governable human system, all of them larger than the family.

The answers to such questions are varied and changed according to the personalities behind the answerers, as a projection of the respective individual's time-based thought process mixed with desires and feelings towards life. From the optimistic "all-are-well" feeling, it extended to hellish and pessimistic postulations laced with reflecting crystals of fear and insecurity in most cases. No responder or originator ever justified the answer, making them *ab initio* opinionated. Another finding here is that the world almost ends for all life forms when it goes on hibernation, say in the form of ice age or dark clouds blocking the sun's rays for aeons, meaning the sun is still there sharp and shining according to some.⁴ For some, the world goes under water as if the water comes from elsewhere external to it. The rain brings back the same water that rose from the earth. Rain can cause floods and destroy lives, but not all. The question is can the water available on the planet sink the entire planet? Well, in that case still it cannot happen as the spread will start cooling down and water will turn to ice. People can live on ice. It is another interesting factor that Noah didn't carry a live fish in a bowl with him, not even a decorative gold fish in the captain's cabin. Because, it was about flood waters, not drought, dryness, or parching. So, all those that live in water will still be there even when the planet goes totally under great floods or deluge. What a whale of a day it will be for the whales and the smaller aquatic crowd there! The whales would love it if the land-clasped living things can stay away at least for a short period, say, for a couple of million years. But that

⁴There are evidences that humans survived ice ages according many scientists. According to the author they not only survived but "resumed" their journey without intellectual interruption.

cannot be the way the world will end. There should be some other way. But, then, who says the world would end one day? It is the author who thinks that way. What if the author is right? There is nothing special, except that the style and pattern of national security governance or GBNS, as preferred in this book, may need to change seriously, and now.

The doomsayers love to discuss the end of the world that means end of everything. They come in different garbs. Opportunistic business personnel may make money out of the script—film makers, religious streamers, fiction writers, cult specialists, advertisers, pseudo environmentalists, panic insurers, fatality agents, mayhem tuners, climate fashionistas, disaster mongers, nuclear disaster prodigies, war mongers, bio-destruction forecasters, disturbed personalities, and even the friendly neighborhood spider man.⁵ Everyone feels end is certain by some means or another. Some are in a hurry giving time only for a hundred years more for anthropogenic extinction. Wow! There are some who say everything will be over in 7.5 billion years. That is not a long time from now considering the time the planet had spent so far turning like an idiot on an imaginary axis, that too not straight—but very carefully at a speed the inhabitants and their holdings are not twirled out into outer space.

Among the cacophony of doomsayers, the positive statements get immersed or silenced in loudness. “Life finds a way,” said the fictional character Dr. Ian Malcolm of Jurassic Park, the movie (1993).⁶ It sounded positive. “Come what may, life will continue, not the living” may be what he meant. It is something to be noted while examining the hypothesis that life will never end. It can’t, unless it is one’s own. The fictional character in the movie may have referred to a particular life form, or swung on it, the dinosaurs. This can be questioned, though it is not the intention to challenge the statement. This author sincerely and sapiently feels life will continue, but need not be in the planet or in the form of an extinct life form⁷ even if some of them may make a comeback. This statement sounds like a conclusion; it is not. But the question, “whether life will continue, come what may,” is critical for governance by national security based on the key principle of premising in any plan. In this study, it is about planning for governance by national security. Yes, the study is deciding on national security for which it has to break a question. Will human life forms survive time (Box 32.1)?

⁵The Marvel comics (Marvel Worldwide Inc.) had introduced quite a few evil or negative versions of unfriendly and distant (author) Spiderman.

⁶Fictional charter of Jurassic Park, the movie (1993) played by Jeff Goldblum. In the movie, Ian Malcolm is a mathematician specialized in chaos theory, but the quote sounds is more philosophical than mathematically accurate vaguely hinting at a desired truth as a wish that life should and will continue. It is also perhaps the movie conveyed to the author as a message. But, dinosaurs coming back? Whatever, the quote covers the entire life forms not just humans alone.

⁷There is a belief that extinction of dinosaurs altered the circumstances in which they lived was turned the course of life by the cause that extinguished them. That perhaps led the way for humans (the modern intellectual dinosaurs) to come up. Well, that doesn’t matter. See Box 32.1.

Box 32.1: The Big and Small of Survival

Dealing with sapiens and their future is an intellectual engagement as it is a heuristically disguised wish fulfillment. But, imagine. What if the world was not hit by a wandering asteroid without inhabitants and hadn't wiped out the dinosaurs. What would have happened afterwards—and how might their presence have affected human mammals? This is against the theory propagated in this book. It is against the “would have been queries.” Just break it for a moment as a passing reverie. Think of it highway hypnosis. Or the travelling asteroid was a game of chance. It was the kind of cataclysm that one can scarcely imagine. An asteroid 15 km-wide (nine miles) was said to have slammed into planet Earth 66 million years ago with a force equivalent to about 10 billion Hiroshima bombs (well, give or take a few million). A radioactive fireball seared everything for hundreds of miles in every direction and created tsunamis that sped halfway around the globe. By the way, was there a sea at that time? Even the atmosphere may have started to burn, and no land animal more than 25 kg (55 lb) would survive; in fact, around 75% of all species became extinct. The so-called “non-avian” dinosaurs didn't have a hope, and only the small, feathered flying dinosaurs we know today as birds would make it through. This also means it is not the fast and furious but swift and tiny that can survive holocausts and other extinction catastrophes. Humans are tiny compared to dinos.

The question is, “Will ‘now-there-are-humans’ become ‘now-there-are-no-humans’?” The answer to this question is important in premising national security governance.

32.2 Premising Destination—Critical Question in Planning

Premising a plan means looking into and through the time span for which the objective of the plan is applicable. Premising helps to identify the factors that influence the plans and forecast the methods. The forecast or the assumptions about the future that will lead to the methods of intervention are generally known as planning premises. It is time-functional. Accuracy of the time is critical to the planning process to maintain direction during intervention towards the goal which normally is a distant object in national security governance. The time functionality of premising is not only about the future, but also looking into the time already elapsed or became irreversible. One may call it past. More than the irreversibility of time already went over or the time yet to pass and become irreversible, the time for a plan is the span it will be alive throughout for the purpose of the system that has been alive unchanged. It includes the time elapsed too, though the plan is under preparation only now. Premising therefore has to take into consideration the “then, now and

then” time period relative to the entity, the organisation, and the end objective, the goal. The “then, now and then” premising is important to know for all the planners. That means everybody who is engaged in an activity that demands a plan. The span may even extend to the irreversible time, if the purpose is there. This is applicable to any organisation or human system, from family, the smallest, to the nation, the largest. When one talks about family values or “honor” (the key ingredient in honor killing or acts laced by sedition), the time span will be clearly the period that has been carrying and will carry the concept or value that is perceived. But where are the ends in a family or national governance?

Governing a family is not similar to governing a nation; nor can it be taken as a biomodel to assess the efficacy of governance with respect to a particular individual in governance. But over the world, the family conduct, deportment, and demeanor of those in authority in governance of nation, generally political leaders, are discussed, at times, when national governance is questioned or supported. Many political heads are eager to prove that their family lives are good. Yes, there seems to be a link between governing a nation and governing or managing smaller human systems, though the principles of national security as discussed here are exclusively for use in governing a nation if the concept is acceptable (Box 32.2). Even otherwise organisation can take cues from national security principles and modify for applicability in other scenarios since the purpose of any governance is the well-being of stakeholders, the people, and the organisation.

Box 32.2: Look at the Smaller to Prove Big is Not Good

When a person’s ability to perform in a job is questioned or criticised, the arguments will include his or her incompetence or negative demeanour in a lesser job assignment. The problem is the latter is past (then), but the questioning is targeted to the present and future (now and then). To bring both the discussions to the “now” phase, performance or demeanour in a smaller group is discussed as a model. This makes a person’s family demeanour or alliance with other groups a point of discussion in national governance shaded in positive or negative contrast. This shadows all forms of organisations as biomodels for governing a nation. But is it important?

A government may encounter two difficulties in premising the period of governance—the length of the period that is not yet irreversible and the past, the length of the period that has become irreversible. They are different tasks for various reasons. There has to be sufficient expertise in the planning team to assess the two different scenarios. There is also the third one: the time getting elapsed or becoming irreversible during the preparatory period which could be very long in the case of national governance at times. The United Nations Conventions on the Law of the Sea (UNCLOS) in the present format (UNCLOS III) took 36 years (1958–1994) from the beginning of the first meeting till the date the third and final one became effective. For a nation, it would take the time plus the domestically required

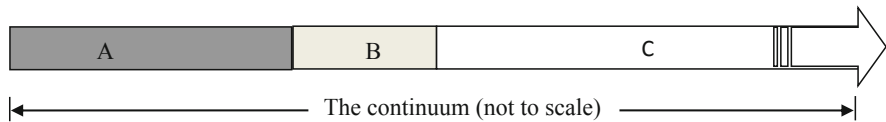

Fig. 32.1 The time functionality of premising. *A* Irreversible time (passed over). *B* Premising and planning time (present ongoing). *C* Intervention time (intervention awaiting)

preparatory (elapsed) time once the country ratifies it to make the subordinate domestic law. All these can drive home the importance of premising a plan as well as the need for reducing either the irreversible or the one forward. It is technically advisable to add on to the irreversible time. It could also be added for the time ahead. There are reasons for both. Here the idea is to limit the static time to avoid loss of practical planning time or intervention time which will impact target date results. The time functionality of premising is given in Fig. 32.1.

Next step in premising is identifying stakeholders and their preferences. It is easy in national security governance because all citizens along with matters important to them (for example, the environment, belief systems...) distributed globally are stakeholders in national governance.⁸ Premising is not simply forecasting, though heavy intuitive decisions will come to the fore while attempting it. Scientifically and mathematically supported intuitive bearings always inhibit any decision making process.⁹

So, ultimately premising in national security is finding about the time passage through which the nation has been going; in other words, the continuum factor and the system impact of the environment of the continuum on the national human system and its effects in future. Premising for national security has similarities as well as differences with business planning. Nation is a macro-concept relative to business, but planning is a business subject, though the term is in usage in national governance. The procedures and steps may be more or less standard for business, but for governance of nation things change very fast based on feedback and prevailing ideologies. Therefore, the similarities include the basic structure of the planning process as the first function of management. But it is important to understand that national planning has to be seen at its highest level and accordingly with decisions that give weightage to national security elements and terrains and the trade-offs associated with the choice. The major difference is in understanding the period of planning. An organisation is like an individual. Individuals manage it. It has a definite end. However, a nation will have a definite end to its continuum profile, but not as a nation as there will be humans and human systems.¹⁰

⁸Paleri, P. (2020). *Corporate social responsibility: concept, cases and trends*. Cengage Learning India Pvt. Ltd. pp. 31, 62, 93

⁹Paleri, P. "Management by Intuition." *Annual brochure of the Indian Coast Guard*, eastern region. Chennai. 1991.

¹⁰Paleri, P. (2018). *Human investment management: raise the level by capitalising human*. Springer Nature Singapore Pte Ltd. p. 15.

Planning deals with future ultimately. Looking into the future is possible using human intellect. But there are many limitations. That's why planning needs to be premised. One of the problems in premising is estimating the time span of the plan. In national security strategy, it is suggested that the plan may be treated as a continuum sans interruptions and breakups. It means as a never-ending premise.

But in general, especially in corporate governance, premising is done through various processes based on the nature, tangibility, controllability, elements of certainty, intervention compatibility, correctability, and so on. National security premising goes through all these processes. The most important of all that is not mentioned here is the time span for premising. This is summed up and tabulated with premising aspects at 32.10.

32.3 Sapien Identity

Who is a sapien? It is a good word and worth calling the humans spread out factorially between the two genders (male and female) where each one is different from another on one side in the mode of differentiability, and on the other, in binding singularity as a species of formidable strength relative to every other. There are trillions of other species, but humans can stand separate (of course, in human perspective, others may not agree). They derive the superior potency for survival from neural intellect that improves progressively through the stream of evolution into sapiens.¹¹ A sapien for this study is the present day *Homo sapien-sapien* sans the tail *Homo sapien*, standing exclusive by time, which can be aligned in a unitary civilization in the format of an advancing worm tunnel where one can always overtake another through intellectual prowess along one's track without having to eliminate or disturb in any way the one ahead. But they are not aware of it yet. To survive existentially, a human doesn't have to push another out of the way according to their neural design for differentiability and the demand for interaction being an interactive species. But the singularity design counters it. This clash is expected to continue throughout. But against their argument of destruction, it is the differentiability factor that will show way of going over the limitations, which the progressive evolutionary dynamics take care of. This also indicates a position for humans to be sapien, the ultimate human still evolving, who can cross over the destructive belt, exemplified by many life forms, such as the dinosaurs (65 million years ago) or more recently declared Saudi Gazelle of the Arabian Peninsula (2008). The sapien is the present day human in the worm tunnel that in all likelihood may stand firm at the verge of extinction without surrendering and crisscross the belt and survive even if the planet disappears. In Latin, sapien means wise; this book uses it as transformed human with positive survival wisdom, where the individual partners in the survival of others along with self.

¹¹ Author's view.

Homo sapiens have been here for long. According to some studies, the first *Homo sapien* belongs to the *Hominin* Lineage *Sahelanthropus tcahdensis*. That was around seven million years ago and the present day humans still call themselves *Homo sapiens-sapiens*. It is time to have an intellectual shave, buddy; one doesn't have to look for any other reasons. Many generations of evolutions or what the author calls evolvements¹² later, *Homo sapiens* at the n^{th} factor and hence a sapien can be said as the n^{th} human or Human_n (H_n) or human2.0 whatever one may like to call. And the H_n is the sapien, the human who can think and analyze his or her decisions by self beyond what the *Homo sapiens* could and improve themselves gradually for another period seven plus million years ahead into, difficult to say, but better than before at any given time. That makes sapiens a never ending but transforming for the better exclusive life form.

32.4 Sapien World

Sapien humans or sapiens in short (as the author would like to name the present day *Homo sapiens-sapiens*) live in the world which is the Big Rock No. 3 from the Sun. They sometimes sing “we-are-the-world” or something similar and go to their caves happily thereafter forgetting the lyrics and the ideology behind it. The world is their abode. To that extent, world is the place the entire living things survive as of now. No, there is no one else who lives outside the world from the point of view of this study. There are no aliens nearby. Humans are alone perched on some parts of the funny rock as if in a ship wreck. Just don't understand why they are there and why they are making so much hullabaloo on matters wrapped in existence. Lost on a planet in an eternal universe itself is chillingly orgasmic. So imagine about those who are lost and degrading perched on parts of the lost planet in claustrophobic holes called nations keeping separate from others and calling it a right? Humans, whom this study recognizes as sapiens presently, are also included.

But who are these sapiens? Actually, they are extended *Homo sapiens-sapiens*. “Since when *Homo sapiens-sapiens* can be considered sapiens?” For this, one has to define sapiens. Sapiens, according to this study, is the term considered or recommended to be considered for the *Homo sapiens-sapiens* since 2021. According to the author, a sapien or a sapien human is an advanced *Homo sapien-sapien* continuing as a species for the last seven million or so years manifested in a continuum in the evolutionary scale. The evolution extends into time seemingly forever. The members are changing and their intellect is enhancing, though may not be strictly proportionally. It is difficult to experiment being a continuum where the

¹² Evolved generations. Evolvements is Author's term to explain it is time for humans to mould from that skin. Under the law of invariance the changes of evolution will be visible only after many evolvements of the specific life form. Incremental evolution is hard to measure though there could be quantum metrics.

law of invariance is very prominent. In such a continuum, every human is singularly fashioned by differentiality. But is there evidence that humans are more advanced and can break the belt and become sapiens as mentioned here, far advanced intellectually in reasoning and thereby more responsible in dealing with fellow humans? Well, it is possible according to the author. There are the following reasons: (1) what if there are sapiens envisaged here already among the people, whom one cannot easily recognize? (2) 2021 shows certain progress that has never been seen among humans to consider well-being for all through governance. A random look at the behavior of the world population in 2021 may provide certain clues about an intellectually advancing human system (Box 32.3).

Box 32.3: Sapient Human

For the first time the world handled a pandemic situation as a developable model for the future at lessened panic in a reasonably matured manner in spite of throttled decisions in the pandemic history of the last 5000 years.¹³ People and their governments handled the pandemic times in a relatively professional and sensible manner (barring the occasional hues and cries natural to humans) through participative, interactive and involved governance. This was the first response so far from a world population to a pandemic disaster without attributing the blame to the carriers or presumed carriers, in the most determined and distinguished manner and making effective use of the opportunities including converting the threat. Humans who know and matters worked collectively and individually whether under natural greed or otherwise to develop antidotes in the shortest possible time. Some of the people may have understood that such periodic pathogen bursts actually clean up and equip life for physical continuity in the target species. Yes, there was also business behind it. Why not?

5 March 2020, perhaps would have witnessed the last war (a wild wish?), the Syrian ethnic wipe out that is still burning. The reasons attributable to it and those similar still continue and will reflect in future conflicts in the absence of severely blown out wars within the unitary civilization of the human system. The date is marked for ceasefire with ammunition still available showing it was not to equip and recoup for another. Probably it showed the way to respect the Nagorno-Karabakh issue (according to the author's amateurish belief). All these and more support the author's quote, "war is over. . ." Yes, humans have qualified for sapient status as per the definition. Now it is for them to prove different from those who were behind them as *Homo sapiens*-

(continued)

¹³Since 3000 BCE, the assumed date of the earliest known epidemic which was are regional pandemic spread out in Hamin Mangha and Miaoziyou in a world that was still demographically picking up. The pandemic would have killed an estimated 14 o 45 million. Epidemics and pandemics plague periodically. There should be a reason.

Box 32.3 (continued)

sapiens. If so, their offspring will be advancing further as humans, “one for all and all for one,” in the quest for well-being and the ultimate continuum. The binary axes will still be there. But as on today (2021), the mental stasis of a sapien must be more advanced than that of a *Homo sapien-sapien* of yesterday. The world cannot wait for them to change evolutionarily but can subliminally stimulate them to transform to sapiens as projected in this study.

Many people consider 2021 as the most wretched year. But for the author, it has been a great period to test many hypotheses about human well-being. The response from the people and their governments was relatively or rather surprisingly admirable. This is especially so when the lifespan of an individual human is extremely negligible compared to the lifespan of human life. 2021 was good for human life; it induced hope in the future of sapien life.

This study advises humans to behave as sapiens from now on by personality transformation exclusively to understand the subjects of national security governance using their power of advanced intellect honed in time. They are humans and it is their well-being by governance this study is concerned with. It is not a direct subject or focused on target, but moving end objective. This is important because when it is a case of research, it may be necessary to separate sapiens from the concept of the world when their end is studied.

Human race has to be seen differently from the concept of the world, as the planet. Then only the humans can rehabilitate themselves when the planet calls it final and ends, which it will, much before the solar system comes into black smokeless oven, what some may call a hole.

32.5 Story of Life Extinction

The study of national security in a people-centric manner does not give any clue that humans, who are considered sapiens from now on in this study, will end one day—even if the planet is destroyed. Human life could outlive the planet. But examining the purpose of human extension beyond the planet or even otherwise—by withstanding calamities of the extinction variety—is not the purpose of this authorship. But it is oft spoken about. There are men and women who walk around in circles holding placards that read, “The world is coming to an end,” at visible corners of the world. They normally do not mention the date, but there are some who may even give a date. Most of them are not sure about the date. But generally everyone seems to be sure that the world will end anyway.

In the long run, it is about two issues: whether life will go on and on or will it continue irrespective of what may happen to its abode, Earth. There is one more question which can be taken as secondary: if life continues even after the destruction

of the abode, then which life form will be the survivor in continuity? The answer to this question is critical to plan for governance towards well-being *ab initio* even if it is going to be millenniums. It means whenever governments will engage in GBNS seriously and focused, the end goal should be for eternal continuity and not mere short- or long-term sustainability.

Scriptures of all kinds talk about it too. They go one step ahead. They tell exactly how it would happen and what the God's alias the powers (force?) will do then (Box 32.4). The belief systems are not standardized or uniform. In some system, Gods will work together; in some, Gods will go to bed for a well-deserved slumber for a very long time. No, no God goes to Camp SS to play golf and sip beer. The credentials of such premonitions could be questionable, but it is a fact that everyone believes the world will come to an end one day and it will be according to the God's will. There doesn't seem to be anybody who denies it, except the author. The reality of life is that it started only once and is ongoing as a continuum process. The clue about the future partially lies in this statement.

Box 32.4: Power and Force—There Are Difference

Power is spent energy; energy exists. It is time functional. Force is an interactive result between two "matters". Power expresses work that contains force. Force and power can both be described and measured, but a force is an actual physical phenomenon, and power in itself is not. Then what about god? Think in "how to" mode. The clue: god is not unreal (author). Lemma: if this is true then the term superpower is not appropriate. It is in the domain of irreversible time (spent time). Superstate is achievable by NS_{\max} .

This study intuitively believes that the human race cannot be wiped out even if the planet is destroyed without trace—if it is not going to happen within the next few hours, days, years, or couple of millenniums. There is a possibility that the world will remain healthy for a comparatively long period, becoming healthier day after day, and even if destroyed, the humans will move out to relatively better pastures to rearrange their lives on surviving the odds at the time of destruction of their very own planet. They will be fit for it at that time.

32.6 End of World

The world, as sentiently perceived, is tertiary in meaning: (1) the planet Earth where life sustains, (2) the planet with the life forms of all kinds, and (3) the human life alone. Discussion about end of world raises a few questions in the first place: which world? Is it about all the three or one or two among them? There will be many questions a researcher will seek answers to based on each one of the primary questions. The first look is on the planet Earth along with everything on it.

There are many ways the world could meet its signature end. Before that, one could examine how the world became what it is. One way for the amateur examiner is to look at the conservation of energy and irreversible changes in entropy that says anything that starts will also stop. This takes the seeker to a new trap door which states, “The real clue to the end lies in the beginning for everything including concepts relative to human intellect, where intellect is the neural design leading to common and individualized perception”. End could be predicted by observing the beginning is one of the hypothetical ideas prompted by this study. There cannot be something that has no beginning and no end.¹⁴ This also gets modified into another statement that everything that begins has to meet with an end.

At this juncture, it is necessary to appreciate that no one is concerned about the silly human except the silly human itself, that too to some extent only. The silly human cares for oneself more than others by default, similar to other life forms. That is the way life forms are designed; that is the way it should be even if humans have to “design” humans beyond and external to reproductive techniques practiced on bed and elsewhere. Other life forms don’t care about a bed or bedroom. Reproduction is not intended designing. It is a kind of extraction. In fact, humans even damage their offspring by modern techniques called caesarean deliveries denying natural process of microbiomic transmissions that are healthy for life. Other life forms do not do that. That is mentioned in Chap. 24. This observation leads to an interesting thought process about survival. Can it be the humans who are the weakest among life forms physically or, rather, biologically? Look around. Do rabbits run dispensaries or at least keep first aid boxes in their holes?

As far as the experiential universe, where the human system is negligibly and innocuously invisible, is concerned, it is not a big thing that only cosmologists can understand. But they are the real masters of the universe who can find out and explain. From their explanations, a person like the author can appreciate within extreme limitations about the beginning of it all. In an undemanding explanation, a simple pendulum in the physics lab in the school can come handy. If there is a problem to appreciate the swing of a pendulum and why such study is carried out, then visualizing a swing in a children’s park may suffice. Or one can shift to the visuals of a simple explosion, say of an egg or a glass ball in perceivable slow motion on a video. Once ready, watch carefully those broken bits of glass or egg move away from the centrum of explosion sans gravitational pull between each piece as they are moving relative to earth’s gravitational pull. After a brief moment they fall to earth, meaning the ground. What will happen to them if they are in a situation controlled by the gravity developed between each other and balanced within through invisible webs? They won’t fall down as there is no down at the end of their outward journey like a swing, but will swing back after stopping at the edge till energy of the

¹⁴There are many books and statements about things that have no beginning or end, but exist. It is a kind of view point that the thing exists but we don’t know how it began and how it is going to end. Well, such statements may not help in national security governance, but need to be seen in governance when well-being becomes part of perceived security.

explosion balances and contracts. The reverse process will start towards the center of explosion, the centrum. It will finally end and the energy will be replaced for the next explosion. In this conundrum, the planet will end much earlier than the “universal capsule” ends. There is no complex science or maths here. Anybody can imagine and visualize the beginning and even add the end on to it by self. That means the world ends in between. It also means neural intellect which would have shaped well by that time may make sapiens to find other abodes and struggle to survive as they are now. It simply means the GBNS on the ground should be based on the central conceptual appreciation that humans will never vanish in a short time even if their planet goes bonkers. Intellectually, they shall overcome the destruction limits and cross over it. The author believes humans are already in a state of doing such survival feats. It also means a continuum force gathers more mass. Planning for continuity (not exactly sustainability) gives the edge.

There are many predictions about the end of the world since the earliest times. The people have heard about it. The belief system that the world will end with or without warning remains like a premonition in the human mind. Some are serious and frightened and also frighten others. The projections about the end of the world do not specify which of the three worlds in the tertiary format will vanish. All in all, it looks the projectors meant the second world: the planet along with its life forms including the sapiens. It can't be.

It will be interesting to see how various predictions lead to the conclusion on how the world will end. The main cause or supporting factor is the amazing order within the disorder that people see. There is disorder, which is true, among all those the people say. The conclusion that the world will end is true but doubtful when the orderly process of the big bang—or whatever bang it was—was examined in the acceptance mode. Can such an early system destroy within? It is not acceptable because the perceived or pronounced end cannot be the end in reality. The end that leaves behind ways to continue afresh is not an end, but more a refresh, a kind of reset by nature. Both are noncommittal, regenerating and nullifying the end. It is not the predictions and alarms that lead to the conclusion of the end, but the fact that these predictions point out which is uncertainty and within this uncertainty lies the information that it is all about human race and not the planet as such. The deadender doomsayers are predicting primarily the end of the sapiens, and surprisingly in this study, the author insists that they, the third world in the list of three, are the one who are not going to end looking at their survivability aspects. Individual humans will die anyway. So what is special about the end? Life will sustain and sapiens will continue. So can it be said that humans are the ultimate and the evolution now on will focus not on species transformation by branching out a la the chimpanzee gate but on regular track? If so, God will retire permanently (now on vacation) one day, after pulling the lever of the ultimate auto mode lock stock and barrel. The sailor in the author will say float, chain, and sinker. And the sapiens continue—individually dying enroute.

32.7 End of Sapiens—Random Prophecies

Yes, individual sapiens have to die by sheer default without which the sapien system cannot survive. But how will they die? This is not a serious question because for everyone there is a signature death (Chap. 19). In 2005, *Hindustan Times*, one of India's leading news dailies, published 10 dangers to the world and human.¹⁵ They were death by catastrophes. According to the scientists, the probable catastrophes the world may face in the next 70 years (2075) are too varied; the report states them. They are articulated below with a pinch of reality check exclusive to this study.

32.7.1 Terrorism

Considering the society today is highly vulnerable to terrorism, a major attack with WMD cannot be ruled out. The chance for a major attack is very high.

This study does not think so. Terrorism was the weapon of the weak who could afford it. The weakness of the weak is mainly the perception of the social system. It is altering the elements that hold the anteforce. Terrorism costs money and heavy capital investments besides physical fatigue and resistance to method inertia (repeat of a method that is no more relevant). All these may change the architecture of terrorism in the social evolution. There are more reasons too. One of the solutions for terrorism is to deny rewards. It is a game of uproar—banging the door under sheer helplessness. People are getting over it.

32.7.2 Viral Pandemic

The probability of occurrence of pandemics is increasing. The chances of human death are said to be very high.

Pandemics visit regularly like the contracted home cleaners and improvers. The Covi19 is on at the moment (2021). Yes, it accelerates morbidity; so are traffic accidents. Human awareness on pandemics and approaching them is improving.

32.7.3 Super Volcanoes

According to scientists, every 50,000 years the earth experiences a super-volcano. The probability, however, is around 0.15%. Such explosions can obliterate about

¹⁵“What a Way to Go!” *Hindustan Times*, New Delhi. 17 April 2005, p. 19.

1000 sq. kms of land. The most damaging super-volcano in history was in Sumatra, 74,000 years ago. The chances for a repeat are very high.

The author would personally love to add experiencing a super-volcano a la Mount Vesuvius in the bucket list along with a nuclear war add on or topping before kicking the same bucket. But will they end the sapien? Nay... That contradicts the claim of very high probability.

32.7.4 Climate Change

The report gives it high probability. Greenhouse gases will double by the end of the twenty-first century. Average global temperature will rise by two degrees Centigrade. In the worst case, climate may completely change in many parts of the world. The report, surprisingly, is clear that it will not sound the death knell for the humans on earth. It can, however, cause trouble. But then what is a climate if it can't change?

Is the climate really changing? Or is it behaving just normal as programmed? Even if the climate decides to change, will the intelligent sapiens resign to suffer by it? No way...

32.7.5 Robots Taking Over

This is a new find that may not have caught the attention of the commoner. There are concerns, considered to be a high probability, that robots may go out of control and behave in a devastating manner and enslave the humans to their command.

Wow, it is a bombshell. Robotics technology will catch up fast within a half-century. It is not understood how robots will sustain on their own without their creators. Humans have the uncanny knack of imagining and fantasizing. Humans have already thought of a takeover by robots. But the robots haven't thought about it yet. This reminds the author to regress to his class when his professor¹⁶ told that humans regularly built castles in the air neurotically so that they could move in there when psychotic. If robots can take over humans, the Tower of Babel would have been a reality.

¹⁶Prof. Rooshi Kumar Pandya (1939–2013). Communicator and corporate consultant par excellence.

32.7.6 *Meteorite Impact*

This could happen. A 1.5 kilometer impactor from outer space could cause serious setback on earth. It can kill faster than a virus or the next door mafia.

Well, that's all. It cannot wipe out humans like the dinosaurs even though there are many T.rex equivalents among them. There is a good probability for a hit; but the world can face it with available technology. It is alert about it. The nukes, missiles, shuttles, and platforms are out there. What are they for? Sleep well.

32.7.7 *Nuclear War*

Nuclear war is nil probability (author). People who matter believe that the world has outgrown the time of a nuclear danger. The potential nuclear flash points are considered to be the Middle East, India, Pakistan, and North Korea according to the report and also those who advocate geostrategic deception from authoritative standpoints. This study doesn't agree.

C'mon; don't understate the civility of these nations. They are nations with responsible people governed by responsible governments. It is also important to know at this stage that, according to this study, there was never a nuclear war in the world. What the humans call a nuclear war in 1945 was a (live) experiment (author) of the deranged human system of the period spread out around the world. It is still a war crime. There are daylight evidences (pun intended). One of them is that in the second test the target was changed because of low visibility. One doesn't normally change target in the middle of a war. In the 1971 war, the author's onscene commander decided to call off an attack on an ordered target as it would have caused innocent casualties. The author respects him and his coup d'œil decision.

32.7.8 *Telomere Erosion*

It's possible, but considered to be at low probability. Telomere erosion means wiping out humans by default—a kind of self-destruction by a countdown evolutionary clock. Telomeres are at the end of every chromosome as protective caps. Chromosomes become unstable when they wear out. The telomere is breaking down generation after generation. Over a thousand generation, the telomere may wear out to a critical limit.

Well, this is something that cannot be answered today. The governments have to get into the genomic as well as microbiomic terrain, research, and find out. There are reasons to believe in self-extinction as explained earlier, the mystery of death is an unquestionable default in a life form. An extended version of death, not of individual life form itself, but for the whole DNA life, is very much practical under

this argument. This counters the optimism in this study. It may not be a good way to go. But sapiens may not give up.

32.7.9 Cosmic Ray Blast

Cosmic rays are generated when stars explode after running out of fuel. It is called supernova that spews out cosmic rays that are fatal to life. It could hit the earth in one of the freaky moments. Such blast can trigger an ice age. The probability is low.

The earth has seen ice ages before. Otherwise, it can do nothing when a star gets angry, sulks and holds its breath, and implodes into itself. But humans are stronger than that to outlive an ice age. It doesn't matter.

32.7.10 Black Hole

Another low probability occurrence. The fear is that a black hole like matter may be created one day on earth that will swallow the whole earth. But the scientists are sure such a matter cannot be created in a lab or by accident on earth.

A black hole on earth will be the ultimate self-destructive paradigm if it ever happens. Till then, people may slip into potholes and manholes on the road and, err, may die too.

There are quite a few agencies and organisation that work to understand threats to humans. One of them, the Global Challenges Foundation (GCF), released the identified threats in September 2018. Their report figured chemical warfare, super volcanic eruptions, asteroid collisions, and the looming effects of climate change that can end humans forever. Sapiens beware. For an advanced and responsible human, the sapiens, these kinds of risks sound like science fiction laced with mystery and macabre, but so did weapons of mass destruction and climate change 100 years ago. Such stories of fantasy are still on even today in different shades appropriate to the change of time. Today, people are at autonomous weapons. Masters of fiction in the olden days such as Edgar Allan Poe (1809–1849), Jules Verne (1828–1925), and H. G. Wells (1866–1946) et al. changed the human trend in fantasy thinking with stories of things humans had never seen or experienced. It is another thing that they will never see and experience them. As a student of science in school, the author doubted the Martians' ability to talk to humans when they visited Earth in movies not because of the language they used (Hollywood English) in a live encounter, but the fact that there was no air in Mars for sound waves to propagate. That meant the funny looking nude and ugly Martians would be without larynx, diaphragm, and other sound producing fitments in the throat. Humans cannot think life without thinking about lifelessness. If it is not by survival default, what else it can be?

The naysayers among the humans (Is there anybody else?) will always use the term unknown threats that they cannot clearly hit at. The problem in a study like this

is that one cannot deal with things that are unknown. An unknown threat is not a threat. But the fact is that if the target is identifiable, the sapiens, then the threat has to be around. So it is important to check the threat attractiveness which will lead to the threat. For example, the threat attractiveness of humans can increase when, say, they play with the environment. In that case, threat becomes damage to the environment and the consequences of it. A threat as an unknown one is not acceptable in strategic governance. So those who suggest unknown threat can be asked to go home, find out, and then come back with definite list.

There is a need to be realistic in assessing the future of life. It will avoid misguidance. Research in various fields will be necessary for that. But the ultimate research is to examine the hypothesis subliminally prophesied in this book—that the humans would outlive all situations, even if earth itself gets destroyed by chance. Human systems have amazing survival capability; it is visible. The subject, however, needs serious research. The hypothesis here is prime positive.

Humans have occupied every corner of the Earth. They have proved they can survive everywhere, well almost. Present-day humans are aware of their capabilities and are concerned about sustenance. It was not so earlier. This concern, coupled with human intellect, is an indication about the endurance if not permanence of human life on this planet. People can imagine catastrophic scenarios, not only for making a block buster movie or writing a bestseller, but also for real time planning for the future. Humans are necessary to keep the planet going. They are part of the life forms that will sustain life on the planet. A skyscraper will collapse on its own under fatigue and creep if not occupied. This happens to an anthill also. This is visible in one of the “easiest” structures on the ancient world—the Pyramids. They were in ruins without care of those who built it, the humans. The ruins stopped getting ruined post-governance takeover by the descendants of the same species—the humans. Post-human, biodiversity can be disastrous to the life forms whether flora or fauna and whatever humans left behind. Native and non-native plants can venture into new habitats causing havoc to the environment. Such situation can save some and doom others. In all probability, apocalypse cannot happen as humans are evolving and they can think right to a greater extent from the past being in forward motion. Under such circumstances, the sapiens should go on—they won’t die.

32.8 But Then, Will Sapiens End?

It’s a kind of leading question based on the previous section. It is also not in a hypothetical frame. There are three answers to similar questions: “Yes,” “No,” and “Sorry, don’t know.” “Will humans end?” was the earliest question arising in human mind and circulating among the system population since almost the very beginning of human life with an unconditionally accepted answer, “yes.” That didn’t frighten anybody. They knew it that they wouldn’t be there by then. In fact, they would die earlier. So, they adopted the “me no worry” attitude about the end. Dying early before the real end would have been more frightening. But it isn’t. People know it as

the moviegoers know it would end after some time. They jumped straight from denial to acceptance going through the interim personalities (anger, bargain, depression) at the speed of light to face the reality.¹⁷ That is the power of neural defaults in human intellect. The journey has to end one day; every one is sure about it. People got mixed up with one's own end for the end of human species one day. They believed it is "yes" and those who didn't want to join them preferred to lean back and roll with a "sorry we don't know" answer. The only answer left is the middle one "no." This book answers "No." Blame the author if it happens.

In fact, survival anxiety choked intellectual depth in humans. It found it to be difficult to penetrate into time. Today, people know they will die. They also believe their planet will end and life will finish off, whether sapien or no sapien. Or the planning premise for a government in this frame of belief becomes short-legged. That is till the entity lives. This is visible in individual human (life insurance, writing a will...) or the human system such as the family (writing a will...), government (election preparations...), or nation (time limited national plans—vision 2030, Agenda 2030...). Well, that will be a mistake, at least in national security plan premising. Planners and governments may understand the need for time premising and forecasting the span. This is basically in the world revolving around the axis of power politics (apparent). The other axis on which the human system revolves—bipolar dominant belief systems (perceived), the premising is much longer. They are not sure "how long" the belief system will prevail at the poles. The perpetuity factor thus gets lost in both. The government considers the planning is enough for a fixed time, the belief system thinks, yes, it could be longer but not in perpetuity, and hence, attempts to gather maximum to follow the belief system, if in case it ends—to follow ("don't know the answer" syndrome). In fact, both the poles want to continue in perpetuity, but know it is not possible. That is the truth under the laws of nature. Hence, an employee to political head, a believer to the faith leader, will desperately endeavor to hang on.

Fear of end by death is evident in every move and reflex of *Homo sapiens*. The fear is not only by survival default, but also by the intellectual assertion of death. In other living being, the fear is by default. They don't sit and brood over it. They do not run for insurance cover or in search of a witness to sign the will. They do not care for their families, though most of them live in families similar to human hierarchy. This can be seen starting from the single cellular and luminescent ocean planktons to the guy who turned the other side on the bed along the evolutionary process, as if not in the mood—the chimpanzee, the one behind the humans though branched out.

Fear of humans can be distinguished from their projections in mindless hyperbole. Among them, it is perhaps the fear of death that is normally not exaggerated. Everyone knows about death. This fear in spite of evolutionary knowledge evolution is frozen in human mind from the earliest primitive to the present day sapien, unlike

¹⁷ As applied to Kübler-Ross model (1969) of five stages of grief. . Paleri, P. (2018). *Human investment management: raise the level by capitalising human*. Springer Nature Singapore Pte Ltd. p. 228.

the permafrost over the poles that may yield to environmental changes. Fear of death will make people believe that humans' date with life will ultimately come to an end. Why blame them? But one has to be careful not only in concluding humans will vanish one day, but also in countering it. It could be too sweeping.

In any question that depicts undesirable situations in time, it is important for the modern humans to be ethical and disciplined morally. This statement doesn't demand it, but is made in the context of present day life requirements as human are or at least need to be advancing from traces of primitivism to make life better in very step as it is going to be a continuum story.

The problem with people is that the fire of intellect continually burns in them and the process of experimenting using it will continue by instinct and also for purpose. People will be careful and the governments will regulate many research processes from exceeding the limits that could be self-destructive. But in crisis or lofty greed, people will get into the high-risk mode for high-gain (evident during the gold rush and Covid 9 period). This will be dangerous. But it won't wipe out sapiens forever like the pretty dinos 65 million or so years back giving way to another super species. The dinos had lived for about 165 million or so years. They didn't deserve such a permanent end. Can this happen to human? No, this study says.

That is not so with other studies. Mostly, they point out to a definite end to humans. The latest among such scholarly studies, Yuval Noah Harari's *Homo Deus*,¹⁸ can generate a feeling in readers that humans may be heading to the end under their obsessive attitudes for development and technological advancement. The future seemingly is at stake for sapiens if such a competitive mad rush for development persists. This is where Adler's theory appeals, "Humans want more than what they need." Harari is right. But thinking from a different plane that this author would like to submit, such casualties may not be wholesome. The law of invariance and law of limitations will situate a wedge to self-destructive processes churned by human intelligence as a whole and sapiens will be constrained to play the agent of self-obliteration. Human intellect, the survival tool, cannot extinguish survival, though survival weapon can also be self-destructive. It is meant to sustain it. Human intelligence can be destructive to an individual because there seems to be suicidal default in people. Besides, the psychology of invention itself is attributed to destruction, though debatable. But that intelligence as a survival tool is relative to individual human, not the system human. The collective intelligence of human system is the sumtotal of the intelligence of humans in it if at all it can be validated as a survival tool. There is no unified human system intelligence. That is the reason why this author defies the findings of self-destruction by individual including self- or mutual destruction. Technological progress is a human pastime. They are fidgety in activity. That is not their fault, but default. It is there by default seemingly to save the system, not the individual element of the system—the individual human. Therefore, an individual human cannot destroy the system human. So chasing technology is default-impelled. Probably, the default is meant to hone the intellect or upgrade it

¹⁸Harari, Y. N. (2017). *Homo deus: a brief history of tomorrow*. Vintage.

as a survival tool. Therefore, with assured upgradation of this sort, the probability of humans destroying themselves to total annihilation of the species if at all is reducing with the advancement of time and will be absolutely nil when the critical time is reached. That means sapiens will be a never-ending ultimate in life format. Human survival tool will help to sustain the human system, not block it. There is nothing shocking or laudable about it. It is natural.

32.9 Reversing Natural Humans: Damaging Experiments

This study makes an effort to change the *Homo sapien* behavioral attire of humans to a more responsible and concerned *sapien* human from 2021, the year of the pandemic renaissance, expected to continue till end 2023,¹⁹ the wheel over point for a restart under enhanced confidence. It is different from getting out of a long and winding tunnel. Humans have not visibly changed physically and mentally from the old. But they can be turned around behaviorally to show more compassion and better awareness of life ahead. The term “sapien” is a recommendation more than a suggestion for an erudite make up to the human systems from now on with due regard to limitations. The humans will certainly change in their behavior and concerns to fellow humans, though marginally, but unremittingly where each step of advance will be imperceptible at the time of taking it till compounded under the law of invariance. The sapiens have to ultimately keep advancing intellectually if sapien life has to guarantee imperishability or remain non-endangered. Even otherwise, the progress in all respects has to be forwarded in life. In all probability, sapiens won't be endangered for a permanent *adios*. But they need to transform for the better and it can't be at the rhythm of nature. Though cannot penetrate the natural frequency of evolution, the transformation is possible by collective motivation for modification. A sapien is superior to the seven or so million-year old *Homo sapiens* in this argument; people want to be superior. They will change at least in behavior aspects in governing themselves. The author believes. But the problems lie elsewhere, not in the laws of nature, but in human attempts to reverse the natural process in the belief they are advancements. But the good news is that such attempts will be futile and won't endure to points of no return.

This study declares humans as sapiens from the behavioral point of view. Change in personality in a forward looking approach towards global identity and security has to be the first step. The very purpose of declaring the present day human, at least in the author's perspective, is to make them autosuggest the feeling or progress in them towards a more sensible form of life with the concern for fellow humans. The physical and genetical transformations will follow proportionately. There is a link between thoughts and development in humans. It can be invoked.

¹⁹ Author's assessment of back to a covid free normal.

But there are unconfirmed reports that many experiments are going around the world where humans are engineered for mistaken superiority over others in the context of competitive survival. Some countries may view these attempts as preeminent security threats to their survival and those among them with perceived capabilities may indulge in similar mistakes of wading nature. Superman was neither *Homo sapien* nor sapien. Attempts to convert a human into a superhuman are artificial. They can destroy the very purpose of natural and intellectually motivated transformation into something better. It has to be edged on superior intellect for behavioral advancement in interpersonal relations. Unconfirmed reports say there are countries carrying out human testing to create biologically enhanced super humans for military and other purposes primarily as a competitive survival tactics under visualized threats. There is nothing new in such reports because there were similar fool hardy experiments during the Cold War periods and before in the human systems, basically based on mind control, etc. It was a ridiculous attempt worse than the nuclear, biological and chemical (NBC) weapons fad in the past that still continues covertly and insanely. More wars have been fought because of them than with them. An NBC weapon impossible to create, though it reflects primitive mindsets in intelligent humans, but similar depraved reversal by engineering human nature to destroy another is impossible. The depravation list included attempts to make things and people invisible by misappreciating the unified field theory and others and sticking to jackass belief systems. Nothing worked so far. Still humans under paranoid perceptions have not understood the facts. If countries still go on thinking of making fantastic or super humans against the laws of nature, they are still in the *Homo sapien* bandwidth and not broadened further as sapiens, the advanced. They should understand even a super chicken that could lay a tennis ball egg is as impossible as making it wear a jockey. The problem is not that such governance will hit their economic nerves by superhuman fantasy, but they will be sliding backwards on the *Homo sapien* scale while the world is already late to advance for a better life for all. The sapien transformation can help it. Once established, there is time in perpetuity for never-ending continuum of well-being for generations to come.

These experiments are not bound or debatable based on ethical boundaries. They may be called the notions in the pursuit of power. But those involved are not aware that they are fiddling with nature unsuccessfully and their attempts will only expose them as primitive fossils in modern garbs or time travelers who lost their time, not the ways. Fictional politics is a curse to national security. It is time the nations understand that genomic and microbiomic laws follow the laws of nature and the best way they can be applied to governance is by natural integration in governance. So gene-editing and biome-reversal, etc. cannot create a bionic superhuman, but can destroy the very foundation of global security and stun whatever structure the sapiens are attempting to build on for the world to survive comfortably well.

32.10 Finally—Premising Governance

Premising governance requires the time duration of the activity. Will there be any change in the method of governance? No, only the type of governance may change, but the nature of governance will not. The reason is that the humans will continue to be the socially dependent life form that will have to cooperatively govern themselves as per the original design. They are social species that need to cooperate to survive. Well, they may not cooperate most of the time with each other, differing most of the time, but can't live in isolated holes or coffins until they die. Interestingly, this noncooperation is part of the cooperative life of a social species. This is the specific argument in this study that nonacceptance is a form of acceptance in a human system outwardly.

Understanding how and why cooperation succeeds or fails is integral to solving the many global challenges we face. Therefore, democratic form of governance will remain ever with many alterations in the preferred way of governance—governing through a government. It can be intermixed with anarchy when the people decide to rule directly without a government. It also means the chef is out; one cooks one's own whatever (no, not the goose). The second form, trying one's hand at cooking, the anarchy, can be avoided if humans become sapien humans as mentioned here. It is not possible by any form of revolution or fast track evolution, but probably through mental evolution of the intellect using the intellect which is there with reserve capacity in abundance for humans. That is advocated here.

Governance is continuous even if the governing process changes. Humans will continue in perpetuity, that too as a social species. Hence, governance is in perpetuity. Such governance will also ensure sustainability and the continuum process to go on without change. Hence, the answer is simple. Human governance by humans for the humans has to be a continuum and that means any government that is engaged in governance may do it ideally till eternity that is indefinite. This ideation is only to remind the student of national security that premising in governance is neither short nor long but continuous. Yes, human governance is going to be under perpetual premising and not for any specific term. The time span of governance is forever. Hence, the advice is to premise forever and thereafter apply feedback corrections. That is all about it. The humans have an option if they are wiser and can hone their intellect to think intuitively—they can live their future today if they so desire and premise accordingly their governance. Nothing can stop them.

There are many issues. Soon they will be outdated even if one doesn't find solution to them. There are also issues that will go along with the sapien humans. These are the ones that have to be identified and premised for convenience. Unlike what many thinkers and scholars say, humanity is not in grave danger or facing special problems today (and everyday) unless they want to consider these problems are special. The talks about disruptive technologies or terror fantasies are all easy to handle by appropriate governance. There will be violence in the world because it is human nature. In fact, violence may increase in the absence of war. They can be controlled by rule of law or other means of national security governance. A nation is

always stronger than its people, though it may not be stronger than another. It will depend on its relative NSI which is yet to come effectively in global collective system. That is not a serious issue. But these and similar factors include in premising governance strategically. The world will change. The news of dropping bombs in Baghdad²⁰ on 25 February 2021 will look silly even for those who ordered it. It was *homo sapien* behavior, not sapien human.

Governance has to take care of all stake holders. That means the people, everybody. There are also non-stakeholders. They too are stakeholders according to author's studies. Agenda 2030 has non-stakeholders as the prime stakeholders—the people, yet to be born, the future generations. A non-stakeholder is the eighth variety stakeholder among the 7+ stakeholder typology (Paleri, 2020).²¹ The future generation is a stakeholder who at the moment is not there. But they have to be included every time governments premise national security strategy and associated governance. The salience of such stakeholders cannot be determined at the moment, but can be monitored when they are there and changed as required by planning at the moment by premising properly. The non-stakeholder salience can be decided for the better by those who include them in their plan for governing stakeholders presently. This means effective premising of national governance can ensure well-being of not only the present generation, but also of the future.

Death is an assured format for life to continue. Death needs to be incorporated in premising because people in governance will change. The change can be managed only if the premising is standardized to human well-being as the end objective. Those who replace those who go have to continue with the baton. They have to ensure continuum. That is where premising has to take priority with respect to sapien life span which is in perpetuity. But this may look abstract. On the ground, premising in business or corporate planning may look different. It is easy to apply them to governance also, but in perpetuity (Box 32.5).

Box 32.5: So what is premising?

Premising is planning taking into account the requirements of the future for the assessed time span of the end objective. It's similar to packing the bag for a long trip. But what if the trip lasts longer than the life span of the person? Well, it is simple. The person plans for those who will continue the trip after he or she leaves. In national security governance the span of time is in perpetuity because the human span of life or life is in perpetuity. The intellect of humans will survive them beyond generations. Premising in governance needs to take into account the internal and external aspects, tangible and intangible affairs,

Box 32.5 (continued)

and controllable, uncontrollable and semi-controllable matters. It is possible once the TRU triad and chance elements are examined, national security elements are appreciated and terrain specificity with respect to the governance problem is concluded laced with a touch of intuition. The entire concept national security as defined in this study takes care of premising for governance naturally.

32.11 Summation

The sapien declared by this study is the present day human with the base year taken as 2021, the year this study is provisionally concluded. In this study, the author advocates that any plan for governance by national security should confirm to the sapien's well-being in perpetuity. It is in the belief that the human intellectual ability will develop continuously to overcome the limitations to human survival capabilities. Human intellect is much superior to the survival tools of all other life forms. Sapiens will retain their evolving intelligence and continue with advanced capabilities based on it, not as a different species by branching out, but as a continuum life form with superior survival capabilities as situations demand. It means human life system will survive all odds. Is this an overstatement? Not for the author.

The wars will die out leaving social space for more conflicts in different colors as humans cannot live without clashing within the unitary interactive civilization. The intellect is tuned for settlements under clash and control. In the binary axes format, the axis based on belief systems leads to more clashes than the political power axis, though interlinked. This is evident the world over. Wars are quite localized, whereas violence is not. The axes will prevail, but the polarities can change, though not in the immediate future. There will be no unipolarity. The polar players should know because unipolarity cannot balance by itself.

There are many questions; only question can make people think and get answers. Humans will not be immortal. That is the law under which life exists. The lemma here is that if life exists by the elimination of individual life form, then life should continue for the living systems. There is some evidence of sapien's survival here, even if the system that supports it discontinues. Intellect is the survival tool for sapien forms. It is powerful. Sapiens may find systems that will make them continue. It also reflects in the scriptures and ancient thought processes.

The present day arguments and debates on morality, artificial intelligence, artificial life, robotics takeover, alien existence and such seemingly modern and incomprehensible produces, existent, nonexistent, and fancied should not carry any surprise or undue imports in any of the arguments on sapien survival. They are incongruent and unimportant in the ultimate well-being of human life. All such things, though may sound comfort corners, are part of the window views on passage. They are tools of the time available for the survival quest originated from the jigs and

fixtures of intellect. None of these are the ultimate tools for survival. Survival is by default; humans can do it better using the tools under governance by GBNS if well-being is the target.

Morality is important. It develops as humans advance. It can also be induced by elevating humans. The problem in morality is assessing the right and the wrong. It creates classes in the mind that percolates into the system. Here too governance matters.

This study does not believe future will make sapien humans redundant. This cannot be said for *Homo sapien-sapiens* unless they are programmed or conditioned by themselves to turn to sapiens at a later stage. This study recommends now itself to behave like sapiens or at least prepare for it. It will do well to the human system.

It may not be correct to assume *Homo sapiens-sapiens* is the most powerful life form. They cannot be. They have to be equally vulnerable like others in their group called life—other life forms. But they are the most scared among all. They go through the survival pangs more miserably than others. It is very obvious in the destruction caused by humans. It can be said that humans are the most survival-fit and well-being-deserved among the life forms. Otherwise, why do they put a mask on their face when an unseen virus threatens? Every life form is equally fragile and each has to survive by their default survival prowess. The default survival format differs, but life is identical. The survivability is more for humans as a system. Individually, they are as weak as other life forms.

It is wrong to say humans control the world, especially when they are not able to control themselves even as an individual. But they can develop. Considering themselves as developed as sapien is a recommendation for that. If humans could control, the world would have been already a global system that cares for total well-being.

33.1 Introduction

When “future” passes through “present” into irreversible “past,” any amount of delay to use the present to decide on futures¹ will change the future perfectness of governance. It is maths, where present is nonexistent if it can be taken as negligible, considering it is only a transition period or a kind of warp. Humans call it “time.” But time is more than that. “Time and space are absolute,” physicists will say.² It is true and has to be accepted and taken in governance too for the reason it is physics, the original and only science. Physics rules and nothing rules physics. Physics impacts everything including a small dialogue in a railroad coach. But that is not important at the moment. The absoluteness of time and space needs to be humanized with due

¹The term futures here relates to the multitudinous results of the considered activities in future perception. The result or effects of action in time to come.

²Absoluteness of time and space is a preferred frame in physics.

respect to physics in matters of life's existence for the reason that time can be individualized or systemized for human system application. It is true that human lives are governed by the turning cyclical time visible on the chronometers on the wrist to big towers. Human time can't be absolute as it is a feel of the intellectual mind that they get when it passes through similar to the feel of air over the face while walking or riding open on wheels in the outdoor stillness. It varies by the speed of the individual. It matters over space and thoughts and is relative to the active human entropy that generates the feel of time as it constantly increases. This is science of life, not philosophy. The rate at which time passes for an individual or individual human system depends on the speed and associated acceleration at any given moment created by it. It is a kind of paradox, though.

Humans, therefore, are seen neutrally static in the so-called minimalism of present. But in reality beyond maths, one cannot harvest benefits without appropriate tools. In national security governance, the tools are decisions. But the problems in decisions are that their correctness for application ideally needs to be tested. By that time, "time in hand" will become irreversible. Hence, the advance time and the critical time become extremely important. Here, the advance time is the lead time one should apply for decision making and the critical time is the time beyond which the decision would not make sense and abaft which the cost of decision can increase where the cost is all inclusive of the factors—expenses, time, effort, and absence of other positive things which would have been done. Here, there are possibilities of shades appearing in decision making. Shades appear as vision losses out transiently. In optical science (physics), loss of vision is characterized by dimming of light and changes in color including peripheral vision. Such shades can enter the time concept of decision making. Simply put, the decision making can grey out into shades of dark taking away the color in it. Well, that makes decisions simply third class. In governance, it also means government will be doing a lot on paper or rabbiting talks even in UN, but nothing on the ground. This happens with incompetent or abusive governance. The cause is not incompetence in decision making, but inability in optimizing decision making by aligning the activity with critical time (Box 33.1).

Box 33.1: What is Critical Time?

Critical time is the most appropriate time or moment or span (of time) for an activity including decision making beyond which it may not serve the purpose either totally or partially and before which will add to wasteful tradeoffs (Chap. 28).

A decision made or an activity performed beyond the critical time is not likely to yield the desired result. Decisions made earlier or before the critical time are likely to be corrupt with needless activities. Essentials will be missing making them less effective. Ultimately, the results will be impacted. In national governance, the results are those leading to well-being. In such cases, well-being will be the casualty.

This argument, though may sound incomprehensible, is only to examine and understand the future of human well-being. It has a time (Box 33.1) element in it. Ultimately, it is the quality of decisions and their implementation that will impact human well-being. The critical time is applicable to both. Decision making and implementation are activities. Their quality can be maximized within the competence of the decision makers and implementers if made and executed at the critical time. The decisions made and implemented at the respective critical times will be most effective within the available competence according to this argument. Therefore, and supplemented by the law of invariance, human well-being should always vacillate between the limits experienced by humans today with respect to tomorrow even if the quality of life (QOL) increases. Increasing QOL need not provide well-being totally. Therefore, well-being is not QOL as generally appreciated. QOL complements well-being. It also means future of well-being will be based on the criticality of decision making, but not complexified by any other concept but the nature governance.

Time³

It is difficult to come to a conclusion about time though it can be discussed. One of the ways of explaining time is in the largest or the smallest frame appreciable to human mind against a reference in the universal surroundings. This can be appreciated by the human sentient as life is an entropically dynamic experience of perpetual motion of self. In Hindu scriptures which are relatively ancient and perhaps the oldest, the highest measure of time is a *mahakalpa*. Sources differ as to its exact length, but a common measure is that a kalpa is made up of 1000 *mahayugas*, or 4,320,000,000 years (duality in reference is acceptable). The *mahakalpa* accordingly is 72,000 kalpas (day and night of the Hindu God of creation *Brahma* here the night is called a *Pralaya* (great flood). The smallest unit of reference is a *paramanu*⁴ (subatomic particle). Typically the explanation in the ancient mode deals with energy disposition and dissemination in the sanctity of sacred conviction as appropriate for the period. The smallest time is a *truti*.

Theoretically, in physics, Planck time is the smallest time ever considered possible. It is the time light takes to travel one Planck length. Smaller time units have no use in physics as on date.

What it is?⁵

(continued)

³These are based on different scholars, school of thoughts. The authors view on time is “the feeling that a sentient living things especially humans get when individual entropy changes differentially) with reference metrics for common use (singularity), for example in governance see also (note 5).

⁴According to the Vedas.

⁵By the author.

For an individual human, time is the dynamic feeling relative to his or her incremental variation in entropy at a given time but will be relative to its disposal towards irreversibility which is not constant. It means humans can feel the passage of their personal or individual time differently. That is why the requirement for a reference time which humans have created cleverly from the earliest known periods but gives a misconception that time has something to do with the time frames of the clock or calendar and other similar things such as a wheel. The difference is that reference time moves in equal measure constantly for all whereas individual time varies from person to person. The only constancy is that both times originate from system entropy increase. This makes individual time very private for an entity. Time is the rate of change of entropy in the system that it occupies. But for external commonality it is referenced to by calibration and validation under varying differentials that can be experienced directly or in scientific laboratories. They include rotation of the Earth, belief systems, activity duration (passing a thorn through a leaf), period of non-linear or unidirectional movements (*kala*, the Vedic times), atomic reactions and so on.

Time has no sentient meaning

Time has no sentient meaning for a life form that is not living sensually.

Want to watch the mysterious world of time—author's favourite?

Visit the ocean beach. Stretch yourself in proper plank position without a mat, totally relaxed and breathing fine. It will help you to exercise and challenge your whole body. Now comes author's prescription to appreciate time. Look down at the beach sand below. Focus; blink normal. Millenniums are morphed on those sands. You can read the history of the Planet in those sands if you go prepared with the basic knowledge of how the Earth was formed and what has been happening so far. It is self hypnosis that the author does from childhood—watching the weathering of sand on the beach planking free. Sand, silica or silicon dioxide, is an amazing format many billion years older than any life form. For the author, it is more magnificent and amazing than the ocean ahead a few meters away. A grain of sand on the beach can take a person into and beyond time, if one can feel it. That grain of sand will take you through time immemorial to you. . .Feel it. It is the sand that opens the cyber terrain too. . .as of now. The beach holds the real "sands of time."

33.2 Riding Hellfire and Highwater—Well-Being Ahoy!

The world came through hellfire and high water. It is going through them in a different way, more psychologically than physically or physiologically for humans. Yes, there is nothing physical without a beginning or end that a human mind is not capable of appreciating. But beginning and end are relative; without beginning there is no end; without end there can't be a beginning. (Well, almost, eh? Don't smile).

Whatever, beginning and end if a singular concept, especially, cannot be articulated effectively unless defined in a manner acceptable to human intellect. The problem is, as one knows today, whether time has a beginning or end in the common parlance, that is acceptable to human system governance based on the planet where they struggle to destroy each other to survive. It means one has to drive on a road considering it as a system with a beginning and an end relative to the drive, but not as part of a macro network of roads around connecting without a beginning or end. No sir/ma'am. Beltways, turnpikes, and ring roads are not the network without beginning or end; they too are parts of the never-ending sandwich that began once. That is like ordering a Subway sandwich which is a cut piece of an imaginary sandwich with no end or beginning. It is also not a bite from a doughnut or a similar salty snack, the *medu vada*, in India which is not "never ending."

And if it is there, humans cannot ideate and comment on it now as intellect is stratified, meaning spread more or less equally with marginal development, auto programmed among humans as they continue into future, where future is time not yet irreversible. Humans do not have the kind of intelligence to understand or appreciate the concept of beginning or end, or the theory of everything (TOE),⁶ at least for now. So, for the author, a black hole with all the suns in it is not an end and will not be a beginning when it coughs them up again after the hangover, a bit processed, of course. No theory can be taken for granted, because a theory is an untested hunch or a still or, maximum, a prenatal hypothesis. It will need testing and the tests may have to be identified. The calibration and validation of a test for a particular hypothesis are yet to arrive on the research scene for the difficulty that intellect cannot test intellect.⁷ Till then, it is preferable to believe that everything has a beginning and end if seen separate from each other, which everything is, though it makes the unitary system of whatever it is. This study also believes that there cannot be a single theory that will explain everything which will also demand a definition for "everything." Interestingly, the only way one can understand the success of hypothesis testing is from the simplicity by which it turns out once the test is over even though the explanations are compounded. Remember Ockham's razor?

That means human life forms will go through hellfires and highwaters⁸ based on their designer⁹ conception, seeking well-being unless intellectual ability that doesn't

⁶Theory of everything is a proposed physical paradigm in which the physicists believe that a singular all-encompassing theory may propose a framework of understanding of all of physics, combining the quantum mechanics and classical physics into a unified approach which explains the laws of the universe.

⁷Can a psychologist be sure about the psychology of his client without prejudice of his or her own personality? See Paleri, P. (2018). *Human investment management: raise the level by capitalising human*. Springer Nature Singapore Pte Ltd. p. 7–8.

⁸The term highwater as a compound word is slightly different from high water meaning floods, which also means the high tide. Highwater as a single word means the harassment a person feels when it blows cold in life just opposite to the heat given by the hellfire but equally strong. When used with hellfire it only amounts jointly they cause suffering that humans can withstand.

⁹Designer means exclusive to the individual in the differentiability mode.

require perception of security prevails in the evolutionary inkblot.¹⁰ It is not possible; there doesn't seem to be a superior survival tool to intellect that may only get upgraded with time following the natural rhythm. This is bad on straight line thinking in which what is in store in time comes directly toward human perception and feeling of time dynamics. In this foggy vision, it is for the living humans to make life better, not for the dead or yet to be born or any other perceived force external to him or her. Human well-being is an internal matter. That is why governance takes the shade of internal or individual doing for self, though it looks collective. Governing self by self is the most modern approach for human collectives and the only suitable one if the drive is toward well-being. No other governing form is suitable for well-being except self-governance which is yet to make a mark in the global scenario. Democracy, as it is today or since long, is not rightfully self-governance (sorry, it is true) unless the opposition is balanced with the governing as positive anteforce for maintaining checks and balances. That is one of the reasons why this author calls every system of governance as democracy (meaning people's participation) because it comprises the governing forces and opposing anteforce in the genre of Robin Hood, Spartacus, Naxalites, militants, and so on, or passive, submissive, and slavish political workers or coerced and helpless commoners. The opposition in governance should be part of the government for checks and balance, a positive anteforce also termed proforce in this study.

Present systems of governance are primitive (started early) and similar to human involvement. Humans are not visibly advanced in governance as they lack the capacity for deep thinking. All of them involve people, either participative or submissive by acceptance. If that is the sign of democracy which it is from the days of Athens and even before, this study calls every rule democratic in varying degrees. The only difference is that there is electoral practice today in most of the countries. That makes it a bit advanced democracy. Not democracy per se. It is mentioned before. Present governance system is old Greek¹¹ wine in new bottle where the attractive design of the bottle is preferred to the wine. Self-governance is expected to be collective in future with the invariant mismatches and mistakes repeating to the never attainable perfection. Humans have the grey matter in the shades of dark and grey from the beginning. Human thinking depended on these shades. Human intellect governs human systems by control, resistance, and submission (CRS) that continue today. Go and see any government anywhere in the world.

¹⁰Inkblot depicts the spread of evolution in its pace which is believed to be perpetual.

¹¹It is considered, Athens is the birthplace of democracy. Hence, a reference-point for democracy. This assumption is based on Plato's (428-348 BC) "The Republic." But, according to author democracy is the only form of governance possible in any human system where the people are controlled by the powerful either by demand or resistance. So far there was no ruling where there were not participation of people either by agreement or disagreement. So giving specific names to the method of governance is not acceptable to this study if it is aimed at human well-being. It is the question of who and how provides well-being through governance. It means the objective is the key not the type or process which are meant for convenience of expression and performance.

There is CRS all around. That is reality. The destiny of well-being of humans in future can continue to be in the shades of dark and grey in the CRS mode.

33.3 So, What is Well-Being?

“According to this study” is a frequently used conditional clause in this book. It has become a caveat by now. Under this clause “well-being” cannot be defined. If that is so, how does one see through time to identify how the concept is going to develop? It is possible. In that process the idea of well-being too can be firmed up as this book is nearing the end. Well-being is not a term defined legally. One cannot sue the government under deficit well-being. Well-being is strictly human and how an individual human feels about the life he or she is leading at a particular time. It is time functional relative to an individual human. That means the individual well-being varies between different levels as time progresses. It can happen to any human along the worm tunnel of unitary civilization in whatever position the person is at a particular time. That is why probably “how you doing” gets the same answer—“how you doing.” It is difficult for an individual to explain authentically how he or she is feeling. Because the human brain goes through multitudinous feelings dancing like the Wu Li masters in the emotional matrix that cannot be explained by words.¹² But it can be felt, yes, deeply. Here well-being is a provision of apparent security within the premises of and with due concern to perceived security which a government is expected to take on as its sole objective under governance by national security. That makes it a feeling and experience that will differ quantumly from one individual to another. Well-being is a function of space and time. Does that mean well-being is a complex and complicated feeling? No. A pat on the back or a hug can give it. A scientist engaged in a nationally prestigious and important research fails at the critical moment when all eyes are glued on him and his activity. The person weeping like a child gets a warm hug from the prime minister of the country standing next to him in the wee hour of the day watching the result that had gone bonkers. An extraordinary soccer champ fails to kick the ball into the net in a penalty awarded seconds before the end of the game. His brain explodes with tears swelling in the eye in front of thousands of spectators, some dead silent and some roaring like caged lions. He would have shot himself if privy to a pistol. Instead falls into the arms of his experienced coach like a child and weeps. The concerned coach keeps him close to his chest with one hand around his back and the other behind his head. The player falls on to his shoulder like a baby drenched in tears. That’s well-being. There are

¹²Zukav, G. (1979). *The dancing Wu Li masters*. William Morrow. The book explores quantum phenomena as a popular science reader. The book besides its central theme of physics also leverages metaphors taken from eastern spiritual movements to explain quantum phenomena. In this example, this author considers the feelings of the mind for the mental quantum phenomena which needs to be fathomed by continued research with ample falsifiabilities incorporated. Well-being is such a feeling.

millions of ways people experience it in their life time. Can a government provide it to the people all the time? Yes, sir and madam, through GBNS (governance by national security). Only governments can do that better than anybody. This means well-being is externally given, not internally formatted. Whereas, happiness is totally internal, from beginning to end. It also brings out the fact that the government and the forms of governance are the ultimate role player in citizens' feel of well-being.

33.4 Form of Governance and Well-Being

There are many links between governance and human well-being. But the fact remains only governance can provide well-being to humans. The primary condition is that governance has to be aimed at well-being. Governance need not be with the sole objective of human well-being. Beside, the objective should be well-being based on national security and maximization of it. This is what the concept of security is about. Many of the trends in national security are empirical. Their success in governance will depend on their correctness and the depth at which they are dealt with.

The world has experimented (was there a choice?) with, what everybody says, various forms of governance. Again one can search in the capsule of time and find that all the forms of governance so far were democratic if the term means peoples' involvement and acceptance of the rule with one part opposing it and some remaining neutral or indifferent. Democracy, however, is defined as an elected form of government. Democracy as a term, therefore, becomes a process or activity of governance, not governance by itself in an exclusive format. If that is so, there can't be two or more types of democratic societies such as US and India on terms of governance by selection by some and not election by others through processes that are different. Value to the constitution is value to the procedures and guidelines for governing. Governance as a concept is different from constitutions as the latter can be changed. Electoral democracy is a process change in governance accepted under the constitution in vogue since election also involves (election of) opposition accepted as a norm of checks and balances. It is for convenience of communication rather than proving an explanation which is factual. There are many norms or types of governments on the roll. They are all one way or another democratic as they have the approval of people who are subject to it if opposition is also part of government, which it is in electoral systems.

All these bring the study to the question, "how democratic is democracy?" A process change need not end up in a product change. Governance is process and well-being is the product. The best process brings higher quality product. Hence, the process of governance needs to change if well-being has to be enhanced. But the process of governance had been democratic throughout, meaning governance with people's consent under whatever method it may be—coercive or submissive, accepted or opposed, authoritarian or totalitarian, elected or under conflict. Everything was democracy, hence democratic, meaning with the involvement of people.

The comparison should not be by the form and shape of governance, but the output, the product, the well-being of people. This can be done only by good measure of well-being of the governed. It is time therefore to free democracy as it is now and find a way people can be made accountable to governance not strictly their agents in the government.

33.5 Mismatches in Democracy

This section can be quite contradictory from the perceptions of the reader and what occasionally this study had pointed out in between is that every form of government is democratic unless people decide to rule themselves without a government. Otherwise, they cannot remain compatible with their existential design as a social species with intellect. People will rule the people with or without a government. Democracy is when people choose an agent in the name of government. It is the form which will have every other type of governance so far identified in the human system under various names which contribute to the typology. Every type of government has acceptance of people either by acceptance or nonacceptance. The author subscribes to this when discussing about GBNS toward human well-being. Under this context, the first observant mismatch is in the term democracy itself. But a term can be defined in multitudinous ways depending upon the situation where it is referred to. In this case, democracy is when people govern themselves through a government and anarchy is when they decide to deal with it directly without any agent. The choice is (only) between the two. Here, democracy is one of the two “forms” of governance.

But in the common term in vogue, democracy is a particular “type” of governance entirely different from other types and accepted mostly as the best type of governance which is opposed by all other types who believe what is good for them is better than other types including democracy. Opinions vary on the same issue.

Most of these points have been already discussed. They are reiterated in a different manner to appreciate the mismatches in the governing process in human systems. Accordingly, democracy as it is today is defined as a form of government in which the people have the authority to choose their governing legislation or equivalent rulings. It comes with a caveat about who the people are and how authority is shared among them. They are the core issues of democratic theory. In a democracy, the people, according to the constitution, elect the government. The interesting part of a mismatch here, if one hasn’t noticed so far, is that the constitution is made by the representatives after becoming representatives without election but “selection by whatever means” because there was no constitution in the beginning of the sovereign nation. Is there a snag here? If it is there, every government is following constitutions that were not made as per constitutions. In the real sense, the first government that was not democratically elected according to a constitution did not have the constitutional consent to make a constitution, though it could govern as an agent of people whom people had approved by consent with or without acceptance. Ha! Does

someone get it? It is a Catch 22 situation or contra to what one talks about constitution, democracy, and so on today in various forums. In other words, today, a democracy is when a government rules by a constitution as it is known; but it is the government who has to make the constitution because they are the lawmakers. This catch applies not only in the beginning, but also every time when a government attempts to amend or totally change a constitution whether written or otherwise. In an ongoing nation, it can happen whenever the government changes.¹³ No, this snag or confusion can also be viewed through other perspectives. For example, there was a *consensus ad idem* among those who made the constitution that they would make it. But it was not the so-called democratic process. Second, the constitution made by one government can be technically amended and also has been realistically amended in certain countries by additions and subtractions or by total ripping off. Third is that a government who is amending the constitution is not the one who is elected by the constitution post-amendment but before that. Hence, their status post the new constitution is invalid unless reelected. This aspect brings back the original situation when the government made a constitution that was not there when they were elected. Do all these sound funny or crazy? Constitution that has been amended is said as the original. The original was made and subsequently amended to see changes as they wished. That is where the dog chases the tail syndrome enters. The government makes the constitution and the constitution thereafter makes the government and the process goes on. This cannot be changed in the present system and the system that is going to be as humans has no other means to run a country in a unified manner. Something is amiss in this statement.

Doesn't this mean that the process of changing a constitution by amendment is not valid under the constitution that itself doesn't have a firm identity? That is the mismatch in the present usage of the term democracy as if it is a high flown method of governance. Now, it is important one should not call democracy by different

¹³ India amended its constitution 104 times as on 25 January 2020. It was effective on 26 January 1950, about 71 years hence. That means on the average 1.5 times per year though it is not the right way to put it but for examining the variations in governance under constitution where the government decides for more freedom. The constitution superseded the Government of India Act, 1935. The country got independence from colonial rule on 5 August 1947 but continued to remain under the shade of the Government of India Act 1935. Was it then a continuation of colonial rule under a change of government? Isn't it a mismatch in democracy if that period is democratic? So was the government that ruled India during the period democratic if it didn't follow a constitution?. Secondly and more seriously did that government have the right to make the constitution since it was not elected democratically by a constitution? Worse is when amendments are made to the constitution though it can be argued that there are provisions in the constitution to do so. But some where there are mismatches in the so called idea of democracy when said it is the best in the governance market for civilized systems. Democracy is not a type of governance as it is projected to be. Hence it is better to be taken as another type of governance under the form democracy different from the other form of governance-anarchy. Both forms of governance are accepted by people until changed. Governance of a human system has never changed except for its shades. The core is the same—people governing people through and agent or otherwise. It is to be accepted if governance has to be made more pragmatic and useful to people.

names. Banana is a banana whether it is in one plate or another. The plates may be different, that's natural.

So democracy today is sharing of authority by people. This too the people will decide. People are those identified as the citizens who are part of governance under the constitution.

If Greek democracy is the example still quoted for the present day democracy, the process of democracy has come under various changes and hence cannot be the same as that was before. It demands a different name being a different type. Of course, it is not possible to summon Julius Caesar or his progenies who ran their countries in their own ways of democracy at this moment. But the world can conveniently keep them aside in governance.

There is no type of government that is consensual for all the people. Every type of government is accepted by people, which also means nonacceptance projecting submissive or aggressive behavior of nonacceptance.

33.6 Sustainability and Well-Being

The sustainable development agenda of the UN had ideated 17 goals, 169 targets, and 230 indicators¹⁴ for a period of 15 years starting from 2015 and ending in 2030 as part of the Agenda 2030. The SDGs were ratified in 2015 as the successor resolution to the Millennium Development Goals (MDGs) (200–2015), though not specified officially. The goals measure different aspects of the economic, social, and environmental development within countries. The countries have agreed with the UN resolution to engage in the process of achieving the SDGs. Within the SDGs, the QOL of people is considered subjective well-being (SWB). This study, on national security as defined, considers well-being the feel of the people of how well they are in which QOL is an external agent more than a standard though variable index. But being considered separately as SWB in SDG, such indexing is very much within the acceptability of this study. Beside, SWB is considered for assessing the progress of the Agenda 2030 through national and international agents assigned the task of SDG monitoring. Basically, the Agenda focuses on empirical enablers to explore how sustainable development relates to the way people experience their lives. In fact, this reduces the efforts of the Agenda 2030 exclusively for human well-being. Only difference is that it is SWB achieved by governance by Agenda 2030, a short-term sustainability programme devised by the collective global agency. It is entirely different from the well-being aimed at by governance by national security at national level by national governance.

¹⁴The actual individual unique indicators in the framework. The indicators will be reviewed by the UN as considered necessary. There were serious impacts and implications of the Covid-19 pandemic on all 17 SDGs in the year 2020. It could slowdown the Agenda unless the governments overcome the limitations.

This means national governments have a choice of either aligning SDG governance with national governance as a complimentary stakeholder of Agenda 2030 or add the benefit from the commitment to the output of national governance. The prime duty of a government is governing the nation as it deems fit. The outcome expected is the benefit the people will receive and the well-being associated with it. This is an expert task the governments are engaged in. They can do it by themselves or by adoption of collective resolutions of the global systems and incorporate it in their respective national governance format.

The regime of sustainable development is not national governance, but the nations have stakes in it which is compelling on them by acceptance. SDGs and its follow-on goals and targets are median-term activities over a period, whereas GBNS is perpetual. Governments can take advantage of it. But national governance toward national security maximization as decided by the policies and plans of the governments still becomes the primary objective of governance. SDGs and similar collective programmes in future become useful and supportive commitments for governments. Making progress in terms of sustainable development by governments will be very supportive to national governments in their task to provide well-being to their people. It will not only benefit people and planet, but also the governments in resolving issues in national governance.

There can be fears in some quarters that actions needed to achieve sustainability may force governments to scuttle their own plans for sustainability exclusively within their domains. This can offer resistance from their people. People may mistake that the sustainability programmes under global dominance can force them to change their social behavioral pattern and potentially reduce their well-being even if temporarily. But the covid conundrum has temporarily affected the SDG interventions largely in many countries. It could be a temporary constraint. Long-term programmes normally get caught in the mire of uncertainty, though there are many ways of overcoming the shortfalls and also taking advantage of the weaknesses and challenges. Experienced and confident governmental systems do not get swayed by such matters. The SWB of SDGs, therefore, does not contribute substantially largely to national well-being and thereby to the well-being of the individual citizen, but can add to the objectives of national governance depending on the ability of the governments to turn it around beside bringing the world closer to committed jointness which may open the vistas for global security. It is too early to predict at this stage, though. Sensible governments may therefore align SDGs in national security governance and take advantage of the UN catalyst to rejuvenate governance.

It is yet to be seen whether the well-being expected to achieve by sustainable development is conducive to national security well-being achievable by national governance. In the real sense of it, sustainability is a term that is actually perpetual, whereas Agenda 2030 is comparatively a 15-year term plan. Sustainability of the human system is not a kind of turnkey project to complete and handover to a stakeholder, the people. Sustainability can only be brought by continued uninterrupted governance by national security.

Humans will continue as sapiens, intellectually well-developed, as the straight line thinking shows to survive even if the systems that support them decline. As they advance, they will be able to arrive at well-being identifying new ways. The early immigrants to America survived and overcame the natives in the West who were different but weaker in fire power and backup support, initially by killing en masse the wild buffaloes, the primary food source of the natives. That was the use of intellect at its time. This sharpness of edging over the weak will make humans continue their survival trip within themselves by edging and nudging and pushing and pulling. It is fine because it has the approval of the law of survival. Important argument here is that the law of survival of defeating the other is also the force that will drive humans to hone their survival tool, intelligence, and the power of thinking. This was explained in the previous chapter. They will be still governed as appropriate to the period.

33.7 Relooking Future—Human Odyssey

Human beings were considerably inferior in their physical design to survive in a world where every step spelt danger. Their survivability wrested in the continuously developing mental architecture of the evolving brain supported by genetic advancement. The brain was designed, programmed, and upgraded by evolution to devise survival strategies. One such survival strategy, seemingly the earliest of all, was to huddle together against a common threat—getting themselves organized into groups. They did it well with all the problems associated with such living. Gradually, in course of civilization, nation states emerged as the strongest of all human groups. Compared to other group activities of humans, formation of nation states as formal groups was very recent. It opened up new identities, vistas, conflicts, and turmoil and has been seen in some quarters as a European concept of the seventeenth century Westphalian principles. The idea of nation states became a reality and caught up with times providing identities of their own to chosen human systems in the great club of the world of nations. The process continues with the creation of new nation states and is likely to be extended to the future. Micronization and macronization of nations are expected to be a continuing trend, though chances of integration or merger of nation states will be remote and passé in course of time.

Formal groups based on faith and belief systems move abeam to political systems in a binary axial system with bipolar dual axes of socioeconomic power balance. Originally, the former systems were the catalysts for the latter. Faith can dominate national thinking which in turn can also dominate it. This is an interesting stasis that resonates within the human systems without losing a beat almost like a human heart, though it is not the right example. There are protagonists of faith who still dream of creation of unitary worldwide nations exclusively based on selective faiths by unifying followers of the particular faith. Their success cannot be predicted because faith is much larger than the feel for a nation and its need for a human system is different from the need for a nation. The concepts of faith and nation are seriously

asymmetrical, though, in certain limited cases, compatible. That is where the asymmetry lap dissolves temporarily in symmetry. It also proves that the two incompatible systems—faith and politics, are not only essential for human sustenance and well-being but also inseparable. This is where apparent security merges with spiritual security in absolute absurdity unless someone else thinks otherwise. It is a kind of oddity that may figure on the points discussed so far in this book on well-being. The Adlers among the researchers may take note and challenge. As mentioned in the beginning, contradictions are the essence of truth.

A point mentioned earlier in this book was about considering the human systems a unitary civilization. Though many scholars find the world a human settlement of various civilizations at a given time, there seems to be reasons to believe that the entire humanity was part of a solitary civilization at diverse stages of development. The stages present the impression that there are many civilizations. The idea of multicivilizations in a single world at a given time is more acceptable for people when viewed from their own pedestals of security perception. There is belief that highly developed settlements truncated at times for unrecorded reasons (disorder maximization). In spite of extinction of certain groups even at advanced stages of civilization, humankind multiplied and developed under powerful life sustaining forces. It gives credibility to human capability to adapt to the laws of life sustaining forces on earth and to the consequences of their violations. Within this argument, any clash between the groups in the world is not a clash between civilizations, but a clash within a civilization. Civilization is an entity of human group activity at different stages, and a function of time. It is live and vibrant. A stage will end when disorder within it is maximized. Containing the “disorder within” is important to retain “group security.” Another lesson is that human beings possess amazing ability to survive under their seemingly weak body projections. No disaster or calamity so far in the world has been able to eliminate humans or reduce them to the status of endangered species. They are multiplying against all odds.

Today, colonialism by direct land grabbing using power is history and nations are free within the framework of independent constitutions written or otherwise. They can resist alien attempts and also establish rule of law within. There is no more free land for occupation as in the earlier times. The entire world is partitioned with simmering disputes along certain borders over the land and the ocean. But the world in no way is free. Domination of the powerless by the powerful continues. The attempts of domination and the stages of development of humans also give the impression of multicivilizations. The continuing clashes between the dominant and the dominated, or the aggressor and the vanquished, also project the impressions of varied civilizations. In reality, it is not so. Such differences thrust upon the nation states an informal and vacillating hierarchical order as reflections of the human societal systems. The world has been truly global in concept with respect to human systems at all times. Its societies cannot be treated differently under any time frame. Therefore, what is identified as different civilizations are best treated as the sub-systems of a civilization, but not as civilizations in fragments. For this reason, the clashes are within the civilizations, not between civilizations. The stages of human development leave the trails of survival techniques. It is prudent to follow the lessons

learnt from the passage through these trails. They are long, winding, and continuous. Within these confinements, one has to identify and maximize security as an ongoing process relative to the future.

Security is against threats to human survival aptly perceived, but not inflated. The TMC (threat matrix cube), identified in this book, is recommended for appreciation of threat analysis. It is vital for security assessment and strategic planning. The “cube” does not take into consideration the wild cards: unforeseen events in the world that could cause a major discontinuity or fundamental change in the security objectives. The wild cards are external to it. Any identified threat can be sited within one of the cube characteristics (type) unless accompanied by a wild card.

National security is beyond the concept of just physical security. It is defined in many ways according to prevailing perception. In this book, the concept of national security is defined as “the measurable state of the capability of a nation to overcome the multidimensional threats to the apparent well-being of its people and its survival as a nation state at any given time, by balancing all instruments of state policy through governance, that can be indexed by computation, empirically or otherwise, and is extendable to global security by variables external to it.”

This definition needs to be supported by a mathematical variable: NSI (National Security Index). NSI is the state of well-being of the people of a nation at a particular time based on the aspirations of the ordinary people of that nation. It is perceived to be a measurable sliding index that calls for further research for calculation and application. This book hopefully paves way for it. One of the reasons for the proposal is that it is already in use under various security regimes appropriate to the perceptions of such regimes. Therefore, identifying a unified indexation process will require *consensus ad idem*—identity of mind—among national governments as a prerequisite prior to research on the subject for universal acceptance. Such an indexation, like the fluctuations in a stock market, will point out to the state of national security of a nation at a particular time and date. It will be a valuable tool for governance under audit, especially with people participation.

The term, ordinary people, is a simple statement of innocence. It points at the people for whom national security in its people-centric perception is the only means to maximize the well-being on the path to survival. People depend on their nation for their survival and have accepted its sovereignty providing the will to cooperate in the affairs of the state under the rule of law. They are simple citizens with the power of juggernauts of sorts to participate in national security governance if invested competently. The government has to be aware of them, because it is the enriched power of effective human investment that will lead to NS_{\max} under collective and empowered governance.

National security, being the well-being of the people, is physical, mental, and emotional in character. Therefore, its relevance to behavioral aspects, especially the human needs and thereby their aspirations, is emphatic in governance. Under such circumstances, transcending to the level of self-actualization is the limit when the needs normally break even in the hierarchy. Anything that is detrimental to self-actualization is also detrimental to national security based on human needs. It is at this stage (the self-actualization level), people start experiencing the well-being. It is

a mental activity that impacts on the emotional and the physical plane of the individual. Such a situation is not hard to come by. Its practicality, however, gets affected when perceived security outgrows apparent security, which normally happens. The gap is filled by spirituality and other ingredients of spiritual security supported by belief systems in human vanity for existence and survival.

The constituent elements of national security were examined within these precincts. They are visible through the fog of misconception of the erstwhile Cold War. This book records 16 identified elements that are placed in an informal hierarchical order, though there is no recommendation to study them in that order. The earliest element identified is military security and, the latest in the array of elements, microbiomic security. Each of the elements is live, evolving and expanding. They were identified from acceptable parameters by disregarding those that were conditional to the concept in varying forms. The underlying characteristic of the elements is their mutual inclusiveness. They are complementary to each other and pervasive to terrain-specific environments. Terrains highly influence human life and serve as platforms of evolution of the elements of national security. The book identifies land, ocean, airspace, and contiguous space as separate geophysical terrains, and deeper part of outer space (deep space), cyber space, genome, and (human) microbiome as non-geophysical terrains for the interplay of national security elements.

The future is not clear except to the fact, in a logical paradigm, that the humans will never stop experimenting and exploring. The human element will be influenced within the specificities of the multi-terrain world.

The concept of national security was believed to be military security based on crude military might. This is a serious contradiction in the national security concept. Human beings are designed to survive using their mental faculty. Though designed using the mental faculties of human intellect, the weapons from the Stone Age spikes to those in the modern day nuclear arsenal are extensions of the claws, jaws, etc. of the primate life. Using the more powerful, mental faculty to overcome biological inferiority is, therefore, logical and natural. But is that the purpose of intellect? The answer is for the humans to seek and understand. Even if the purpose of human race is to live without aggression for survival, the pace of changeover toward totally nonaggressive mutual existence could be extremely slow. It is seen in the pace of evolution itself. The argument to use intellect for nonaggressive existence undermines to a great extent drawing on violence by war or terror for perceived security and survival. Military might does not guarantee well-being of people. It may keep the enemy at the border, that's all. Military is necessary, under the circumstances, as an essential instrument of national (global) security within the scaffold of the policy of well-being. This is achievable by transforming crude military might into intelligent and knowledge-based military might. It covers the broader spectrum of national security. The world, at a very slow pace, is turning into that direction. Intelligent and knowledge-based military might may make conflicts result-oriented and appropriate for survival. The concept of intelligent military might is not new. It is seen even in the mythological military order. The mythological wars depicted in the ancient Hindu scriptures *Mahabharata* and *Ramayana* are examples of wisdom in war, though undermined by temporal imprudence at times. Conflicts are expected to

follow certain righteousness according to these epics. The advocacy of human rights even in the battlefield was highlighted in these ancient scriptures whose dates of origin are not exactly identified.

Serious investigations into the subject will reveal that among national security elements, it is military security on which a government has absolute control, whereas the power of the government erodes gradually on others and keeping a strong hold over other elements is not easy. That is another reason why governments prefer military security as their prime element in discussions and dealings of national security management. Another reason is that military security is the only element that is directly related to human behavior. It is aggressive behavior in a situation when a life form is threatened. This behavior will remain with the humans throughout their lives. Like any other behavior patterns, the only way for its retreat will be by behavior modification. Killing in war is not homicide. Or is it?

The wisdom in war is intellectual that includes technological advancement too. What the nations could best achieve is to replace the crude military might of brutality, violence, and dictatorial objective with intelligent and knowledge-based military might of strategic wisdom, technological advancement, and conflict resolution objective. There are many nations that are capable of developing “intelligent and knowledge based military might” toward the wider objective of national security by focused planning. This capability will be a buffer to the security of such nations, if exploited effectively.

The control that a government will have on other elements can be limited under different situations with many other players in the domain. Governments may find it difficult to control the disorderly traffic on the narrow roads to the elements of national security. The competitiveness of a government in providing national security to its people can be ideally seen from the effectiveness by which it could exercise control over the elements. Globalization may have eroded some of the powers of the government. But they can be collectively acquired. Limitations in government’s capability in controlling national security governance arise from constitutional reasons of politics, incompetence of political and bureaucratic systems, power games within, abuse of power, absence of professionalism, inertia in the NSI by lack of development, failed people, and many other negative conditions. Globalization is external to government. Globalization is the result of enlarged knowledge base, information technology, and communication revolution. All these limitations, along with the anteforce, choke the system widening the gap between authority of the government and its accountability. For effective governance, authority should be appropriate to accountability. When it is limited, the government fails in its commitments to the state and may be changed by forces external to it including a democratic election. The next government meets the same end if it is also plagued by identical situations. Reelection of a government could be a sign of success in national security governance. The government understands its success in most of the cases after reelection in a democracy. Beside, it is also symbolic that the electorate is not tossing and turning on the electoral beds as restless insomniacs. This statement is only a thumb rule and needs serious examination based on each situation to validate the state of governance.

Change of government after the first term in a democratic electoral process could be a sign in the opposite. It normally happens in nations where the inertia to NSI is very high. More than the popularity, the governmental systems should be concerned about the reasons of authority versus accountability imbalance. It is more so for the newly elected government that should not be under a misinformed feeling that it is their popularity that has brought them to the government. The reason could very well be the failure of the previous government in NS_{max} governance. The newly elected government could do better, if it attempts to understand the limiting forces in governance experienced by the previous regime. Otherwise, it is bound to fetch the same effect in the next election in an electorate that is normally restless and disappointed under such situations. This applies to any type of government, not in electoral democracy alone.

The interactive aspects of elements are the most intriguing part of their character. It is within the net interactive output of elements the maxim of NS_{max} is depended, because there are many situations where incremental changes in one element may bring an inverse reciprocal change in another. There can also be positive changes. This impact on the net advantage or combined advantage is very important in national security governance. Maximizing national security within the concept of a nation state is an ideal objective for any government. *Arthasasthra* and similar guidelines of statecraft and war in the days of the kings deliberate on the duties of the “king” toward the people of the kingdom (In this study, the word “king” is used without gender bias and is equally applicable to a queen or an entity that rules a country). The kingdom constituted the nation. It continues to be so even today in many parts of the world. Monarchical systems either independently or with elected democratic orientation prevail in many countries. The Italian political theorist, Niccolò Machiavelli (1469–1527), had elaborated about the ruler and his provisions for ruling in his treatise, *The Prince*. Under these deliberations, the concept of a nation is clear generally for this study. What needs clarification is the concept of national security. It can be argued as the security of a people in an organized group ruled by a government of its own kind. It is the duty of the government to provide security to its people, irrespective of the form of governance. The term “security” is further amplified in a larger reference beyond physical security as national security which in turn leads to human well-being. The future of well-being is what matters ultimately in the (probably never-ending) human odyssey.

The threshold of perceived security drops as humans advance in life. However, apparent security, the security that the government is expected to provide, remains more or less at constant level except that the efforts required for maintaining it at a certain level will be more as the world evolves. That means, more efforts will be required from the provider, the government, to maintain the same level of apparent national security with the advances in life. The balance, even at the height of apparent national security, is driven by spiritual security without which there will be no psychological stability. It is more or less by default. Spiritual security and all the forms of human endeavors for achieving it will, therefore, be predominant in the world with advancement, since perceived security level is poised to increase proportionately. Under such situations, demand will increase and the scope and

elements will widen. There will be a rambling conflict of aspirations and attempts of power maximization that will not be easily satisfying. So the government has the obligation to induce appropriate national security threshold by governance in their people. The national security matrix is simple to understand, but the policies related to them can be complicated. Therefore, there is a need to understand and design policies unambiguously. Errors can cause irreversible policy mishaps. There is no solution to a damage done. This is the principle of chaos theory. Only mitigating measures can be taken subsequently. A clear understanding of national security concept, its changing profile and elements, therefore, is vital to any nation. It is also relative to the character and aspect of each nation. The concept of power of a nation is relative to the power of another. However, the concept of national security is relative to its own perception of security. This perception could be different from the perception of another nation, unless the assessments are based on the notion of apparent security and not perceived security. Often nations make such perception on perceived security and not apparent security, because there is no universal definition for national security. But it is important to understand that national power is not national security.

The gap between apparent security and perceived security is ideally the void that will be filled by spiritual security—the balancing force. It enters the void by default and moves out when filled with apparent security. (That is why generally people visit psychics or think of penance for divine intervention when the times are bad). The government even at its best cannot provide maximum apparent security. This widens the gap further. Notwithstanding, spiritual security will flow into the void. The indicators of spiritual security, therefore, could be a monitoring guide for assessing the NSI. These indicators are far too many. Moreover, such indicators have to be clearly separated from those that have been projections of self-actualization—the creative interpretations of life. Some of them may be misunderstood as spiritual security projections for a casual observer. Most of the creative works can be associated with spiritual security identification. In this book, the concept of spiritual security is employed to point out the concept of national security in a contrasting way for better clarity and emphasize that it is apparent security that the latter is dealing with. The perspective of national security evolves from this contrast between apparent and perceived security.

In spite of the findings, national security concept is preoccupied with military security. It is not easy to change, though the changes are apparent in the world today. The changes began with the end of the Third World War¹⁵—the Cold War—that witnessed enough bloodshed in various parts of the world. There are serious disadvantages in mistaking national security for military security. It will be a blooper. The world is slowly becoming aware of it. The use of military to wage large conventional wars in the world is waning compared to the past. The military will continue to be centric to all matters of security. National security is a different concept by itself. It is interrelated with its elements. The net change in the elements is

¹⁵ A deliberate perceptual view of the author.

what matters in deciding the NSI. The changes should be toward maximizing NSI. NSI will be the collective sum of the security indices of all the elements. It is not possible to maximize one element by itself without a corresponding change in another in general sense as the elements are mutually inclusive. That is also the reason why this study recommends that there is no concept called nonmilitary security in this study. Military security is one of the 16 elements and not a standalone concept. Therefore, NS_{max} is a continuous task of maximizing the elements of national security optimally toward elevating the national security index.

The elements are tightly intertwined with each other in the process of governance. There is no single method of managing it. But the objective is very clear. It should aim at the total apparent well-being of the people of a nation. In this process, it may lead to global security as the ultimate objective in a very long period of time, and the humankind may successfully avoid a return to the caves as predicted in the Olduvai theory. The future of human well-being lies in this statement. By all means it should gonna go good.

It also means national security is not about war and fireworks. Nor it is about missions impossible. It is achieving the state where the people feel their needs are met and creating a feeling of well-being with realistic sense of hope about the future. It is about making life worth living keeping future generations in mind. To that extent, it is a futuristic concept with respect to fulfilling the needs of the humans and making them aware of it. It is not a utopian¹⁶ fantasy, though it could be argued to be one.

It is a concept that can be more easily explained by what it is not than what it is. For one, it is not a process that is riddled under complexification of processes. Simplicity in an activity is by the basic law achieving human well-being. The capacity of humans is very limited. Therefore, whatever they can do should be simple in nature. Complexity is a relative expression within the limitations of human capabilities. Taking into consideration the prolonged and ever strengthening human existence and their capabilities to survive, what they have to do for such an objective must be naturally simple. It can be argued. But it may look big like that for an ant attempting to climb a pole. But the task is simple—just climb up. That is an aspect not yet perceived in governance and those who govern. All aspects of national security, therefore, have to be simple to execute, however complex the process or long the time required may be. There is no quick fix solution a corporate executive, a military commander, or a political leader can attempt while holding office. But they all can do one thing in proper: do not fix something that is not broken. National security is a matter of continuity. The problem is in the perception. Because, within these perceptions lie human conditioning and associated vicissitudes of people. Checks and balances go tipping over.

Indicators of national security need to be identified, reviewed, and studied thoroughly. What is important here is to understand the non-indicators so that they are not taken for indicators. That will mislead. This knowledge comes gradually. For

¹⁶Utopia actually means “no place” in Greek. It literally means non-existent place.

example, a much-hyped parameter to indicate a nation's health is suicide rates. A suicide is a matter of mental process among those who commit the act. Just like the way a physical handicap among the people cannot be taken in isolation as a direct measure of a nation's well-being, mental handicaps will need appropriate consideration as required in maximizing health security. Suicide certainly is a mental handicap where a person does it so under social hypnosis, honor deaths, self-punishment under imaginary guilt, as punishment to others, depression, panic and fear, or even an insurance fraud to claim money. Psychologically, it could fall part of a game for a reward often unknown to the victim. Some such acts are simply crimes, others may not be. Can suicide be linked up to genetic security? Questioning a parameter, recommended as an indicator, in this manner at every stage of its identification is necessary before its acceptance. There are so many such parameters that may misguide judgment on national security.

An interesting aspect is that seldom history has witnessed a reversal in the aftermath of an incident whether it is war, terrorist attack, economic depression, disaster, epidemic, or any of those that affects national security. Everything repeats. In some cases, detailed studies will be carried out. Every investigation will end up with contrasting views, each laced with an aura of mystery. The reactions to the incident will slowly dissolve into day-to-day life and forgotten even if it is a nuclear attack. The incident can repeat in a different form as another wake-up call. The cycle continues.

Author Stephan Flynn in his much-involved book stated that despite all the pronouncement post the 11 September 2001 terrorist attack in the country, the government was not in a position to protect the people of the United States.¹⁷ This was from a person who had served in the National Security Council. The first sentence on the first page reads, "If September 11, 2001, was a wake-up call, clearly America has fallen back asleep." It is equally applicable elsewhere, where countries have fought wars one after another or faced terrorist attacks without learning lessons from that. Disasters take place at cyclic periods and one can even predict when it is going to repeat in most of the cases. The amnesic approach of the humans to future with absolutely callous or totally blind attitude to history and the past is forlorn and, at the same time, amazingly close to the behavior of animals toward their past. They forget an incident in seconds and depend more on their instinct to survive. Does this bring the humans as the first ever species in the chain of a long evolution with a brain that is still very primitive and closer to the last of the animals than even the next stage in evolution? Why humans behave like the animals than some more advanced life form in their quest for survival is a mind-boggling question which the humans may not be able to crack if the hypothesis is correct. Because they just can't carry that much in their shopping cart. Humans may struggle through informed governance and find a path through it for development.

¹⁷Stephan Flynn. (2004). *America the vulnerable: how our government is failing to protect us from terrorism*. HarperCollins.

It is evident from the lackluster speech of the President of the world's most powerful country on his second coming on the inauguration on 20 January 2004. Wishful thinking dominated the process than articulated action plans for future. President Bush said that America would be safe with freedom in the countries of the world. Well, what does that mean? According to Flynn, America is living on borrowed time and squandering it. What does one say about the state of America on 6 January 2021 when the Capitol was besieged? Has it hit the bottom? So to what shade in human well-being?

The statement is applicable to the whole world. The events of the world make one feel it is always on borrowed time. But the evolutionary lemma doesn't agree with it. The world should move forward. It should become more constructive, responsible, benevolent, and ambulatory. The process of national security flows through this evolutionary route. The process is too slow for a generation. Adjusting with the pace of this process is very important for the humans to avoid slippage, like in a belt that links two wheels in a drive. National security governance may have to induce the friction that is necessary to synchronize the process with the pace at which the evolution progresses. That will be necessary for sustainably enhanced well-being of people.

The Achilles heel of national security lies in its center of gravity. That again is a collective concept of all the elements placed together. The center of gravity shifts continuously based on changing scenario. Each element of national security has its own center of gravity and that should match with the resultant center of gravity of the concept itself. For stability, it should provide, borrowed from the nautical terms, a good metacentric height to keep the NSI buoyant. While the metacentric height is the leverage between the center of gravity and the center of buoyancy of a vessel in water, the envisaged metacentric leverage in national security is between the center of gravity of national security and those of the elements of national security that will keep changing under changing situations. It is a typical case of leveraging two entities in one system. The longer it is, the more stable the system. In a stable system of governing national security, the leverage has to be identified understanding the centers of gravity of interactive entities in a resultant format. This calls for much specialized studies. This principle is not critical to national security governance alone, but in all group behavior formats. The collapse of an industrial house, defeat in election for a political party when everything was seemingly going right, winning in election in spite of a bad history of governance, a victory in war that turns out to be a devastating burden subsequently, etc. are examples similar to the sinking of the Titanic because of bad rivets—when everything was going fine.

Chance plays a major role in changing the world. Incidences governed by chance like the 11 September 2001 terror attack in the US or the 26 December 2004 tsunami disasters in Asia are examples. Every chance has a cause since a chance event is an effect. The effect becomes chancy when the cause is not known. The next question is, "Can one create a 'chance' event for an accident if in the overall benefit of the world it is better?" For example, assume that a government welcomes an intelligence report that there is going to be a terror attack and allows it to take place with an eye on opportunity to achieve a choice objective—say...? Well, that is a dangerous

question this book dare not ask! But it is sued here to ideate the possibility of chance farming.

All these questions will need independent, totally detached, and unbiased brain banks to answer them all around the world. Because, biased judgments will advocate win-lose statements, whereas national security governance needs to identify win-win or win-hold-win decisions in governance. National security is not about defeating but winning. Winning need not involve defeating. No game can be won strictly by defeating the other entity in national security.

As mentioned earlier, it is the government who should provide for apparent national security to its people. The accountability is extremely high and the question is on the authority of the government, the power it wields in managing its affairs. It is seen that this power is maximum in the aspects of military security, whereas in other elements, the authority of the government is at reduced level. Beside, globalization and other international processes (an agreement, for example) limit the authority of the national governments. The limitations of the governments in providing for national security, therefore, will arise from the erosion of their authority.

Involvement of government in perceived security of the people has to be with caution. It could be unwarranted beyond certain point in GBNS. It means supporting spiritual security, the gap between apparent and perceived security in maximum national security. It will be ideal for a government to support spiritual security in its natural habitats—the human psyche, and not in the governing systems unless rule of law demands. Rule of law is not an element; it is a task of governance. Even a proactive and sincere attempt to erase a natural superstition can cause damage. It has to be guided indirectly. Spiritual security can provide more relief to a human than what the government can provide by maximizing apparent security. Challenging belief systems will always be counterproductive. Beside, the act strengthens it further. The tendency of spiritual security aspects migrating into apparent security elements increases by the creation of a void in apparent security. People will not accept challenges to belief systems on which they survive. The belief systems have to be removed slowly and carefully like unfolding the scaffolds to expose the finished building without scraping it.

While the concept of national security is embedded in all aspects of human systems and records including the constitutional documents today, the concept of global security is in the formative stage and yet to be accepted. There are many issues that are tackled toward providing a better world to the generation next as often appears in the slogans of governments and international organisation. The good order and discipline of the world should be brought by governance and rule of law, not by abuse of power. There are many countries in the world ravaged by war and conflicts still gasping for breath. Many of them are still coughing blood. They need support of the world lest human well-being should become an impossible dream, though the future doesn't seem to be that bleak.

The issues of global security are different from national security, though the solutions could be compatible. For example, the term “war on terror” could be acceptable for the entire world. Disaster security concepts which when shared in the global perspective are equally applicable to national security. The ability of

national governments in managing national security will improve if they could identify the pedestal of global security solutions and view national security from there. The superpower and the United Nations could guide the national governments about the application by duality of the global security solution in national security management. It is in this process that the idea of global security, which ultimately is the process by which the world will evolve into a better place, can be germinated.

The world is fixated on long-term defense planning rather than national security planning under defined and articulated SNS and follow-on NSS. Nations are engaged in appreciating the situation and predicting the future conflict scenario of the world, nationally and regionally and estimating build-up to counter such conflicts. This fixation, beside causing proliferation of duality technologies and weapons, may also squeeze the economy of many nations. But there is advantage to the leading players for whom war is a market. The market needs to be sustained to create demand for products. The question is not the human trauma associated with the conflicts or conflict situations as seen in the last two world wars. But the economy diversion can debase the world economy and invite conflicts that may be difficult to handle. The probable victims have to understand it and take precautionary measures in their NSS. The likely beneficiaries may take responsible diversions for economic advantages.

Economic depression and panic have resulting tributary in war and conflict. Former Iraqi president Saddam Hussein's economic difficulties in the protracted war with Iran (190–1988) made him hunt for money (oil) in Kuwait, which later brought total destruction to his regime and prolonged uncertainty in his country. In a larger dimension, the Iraqi biomodel will equally be applicable to any nation including the polar states.¹⁸ Human casualties in war are actually negligible compared to many other ways people exit the world. Beside the human agony, the world will slip back more than the normal in the backward surge, the standard motion forward as explained earlier in the book. The backwardness can be visible in many of the war- and conflict-ravaged nations. The views of scholars on the subject of the future world are not identical. Most of them are pessimistic and guarantees assured destruction and apocalyptic views. The problems in assessing the future are many and one cannot foresee the future that easily. Even predicting the weather patterns a week ahead is a point of limited accuracy. Long-term strategic planning into the future by predicting the trend may derail at the beginning itself as many governmental decisions prove to be. Accuracy could be availed by seeing the mirror image of the past into the future and learning lessons from the history of the “future.” Unfortunately, as mentioned earlier, humans suffer from animalistic amnesia and behave more or less similar to an animal in future perception. This tendency is visible in every decision-making process by governments in relation to future. They (re)create the past in future under limitations, seemingly, by default.

¹⁸The term is used to explain the bipolar nations that control the polarity of political axis in this case.

Any overview of strategy for future may depend on the propositions as key factors that are expected to shape the process. The parameters will provide the scholars about the idea of the world. If the parameters are wrong or disjointed, the ideas will be nullified *ab initio*. Unfortunately, the nullity will be known only after the future slips into past. It is a repetitive case in matters of governance in every nation. There are ample examples in history. Is it possible to appreciate the future without key factors? If so, it could be a different idea. In that case, the future has to be visualized by evaluating the past and correlating it with the present. The applicability of the past and present to the future could very well be analyzed to understand and appreciate the turn of events. But that is not enough. Once the past is taken seriously for decision making, there are also chances that progressively history will remain without distortion.

The world has been preoccupied by conditions caused by diverse belief systems, each attempting to exert on others as well as transnational corruption and crimes (TNCC) as part of the anteforce. Both are behavior patterns carried from the past and not new, but the people have a tendency to feel as new concepts when attired in new jackets. Dealing with them is under the rule of law nationally and internationally. If the methods are not effective, the world has to find new methods. The involvement of the military, whether preemption or otherwise, will be according to the intensity of the problem. Not far away from the dug up position of exploration, the reasons for such issues could also be found in economics. A change in economic policies could curtail many of the problems with ample geostrategic approaches. A strong government and international system is vital for the problems, which in the world today with advanced technologies and communication systems should not be difficult. The asymmetry between the government and perpetrators of crime mentioned above is increasing in favor of the governments and international systems.

History teaches a lesson that the humans have failed to understand so far—speculations about annihilation of the human race by itself in a distant future will always be distorted by a wild card at the appropriate time. It is not likely to happen. If there is a force that could ever destroy the human race, it will be under the law of nature. Nature is not destructive. Its only concern is energy transfer for conservation that it will do very well. Humans should align with nature instead of getting caught in the process. Nature can take care of itself; humans cannot.

33.8 Future of Governance

It looks humans are born under a common command that “thou shalt be governed from now on.” Whether one likes it or not, “though shalt be governed” is a kind of dictum in the human system since humans are social beings. No one can escape the command of life as long as human system prevails. Because humans are socially intelligent living forms who will desire to manage their lives by themselves either directly or through an agent. There are two factors that govern this dictum: 1)

humans have to survive using their intellect individually and in groups and 2) humans are social beings, not insulated private beings, hence interactive.

People desire to live peacefully, though peace doesn't exist as real or unreal. It is an abstraction for comforting self. Therefore, it is not unreal. Humans may define peace as a state of absence of those emotions and feeling that are irritants to a self-actualized life in a teeming social system where humans are perpetually "sentenced"¹⁹ by birth to live. Well-being thereby becomes a concern for human life. It can only be maximized through governance which people are collectively tuned to. The ideal governance is that of a national human system, the largest organized human gathering with a defined boundary even if disputed. It will have many subsystems. It is the marble jar in the shape of a compact marble globule containing many subsystem—and sub-subsystem—marbles in the diminishing order to the smallest—the family. If governance is considered the only human process that can provide maximum well-being, then it is about maintaining order and system steadiness in a nation, the primary system. The elements of the system, in this case the members of the society, remain orderly, a state in which maximum well-being can be provided within the natural constraints. In this deduction, governance is important. Therefore, to track the trail of human well-being and appreciate it through various shades, whether dark, grey, or bright, it is important to see the evolution of governance. In this study, an earnest and unprejudiced researcher may come across quite a few surprises subject to the law of invariance combined with the law of limitations. If not, one may recheck the two findings: law of invariance and law of limitations.

So how do people govern? On one side there are various types of governance to choose from.²⁰ Among that, lot democracy (the process of governance) is not only considered separate, but also unique and the best. This study doesn't agree with that view point. There is serious semantic dissonance in the term democracy and its usage which is selective and convenient if not innocent or ignorant naivety of the user. Governance is a process. Government is an actor; an agent; an entity...

One has to look through the wall for a change. Who said one can't? It is possible even to see through the thick wall of a nuclear reactor. No form of government can be chosen by all people with identity of mind anywhere in the world. It never happened. It will never happen. There is nothing serious about it. That is the way it is. There will always be somebody who doesn't accept the government or the governance of a government. That means there is no identify of mind between some people and government at any given time. So where is the so-called people's rule? It becomes some people's rule. Here the argument of the demo-supporter may change conveniently that democracy is the rule of the majority. That is absurd. Majority rule could be seen as suppression of non-majority (the term minority is deliberately kept away for the time being because it is a term as absurd as democracy). That is under

¹⁹ Author feels "destined" is not an apt term.

²⁰ Paleri, P. (2008). *National security: imperatives and challenges*. Tata McGraw-Hill Publishing Company Ltd. p.470-75.

the presumption that government can be chosen and through it the process of governance. This hypothesis can be debated. Nowhere in the world there was or is a government chosen by all the people unequivocally. This is based on the human system behavior from the smallest to the largest. It is not an exclusive national behavior. Therefore, considering governance is exclusive to nations is wrong. Any organisation or formal human system, large or small, system or subsystem, can follow the process of governance appropriate to it. But in the concept of national security what figures as governance is the process of national governance. The process is carried out by a government in national governance. The emphasis here is that there is no government that is acceptable to all, and therefore, this study doesn't agree to the hype on democracy, the way it is taken as a separate form of government as the panacea for all evil that people suffer. Don't change the wrapper. So democracy is not democracy as a separate and advanced "form" of government or governance. Democracy is the form of governance when people decide to govern through an agency called the government which in every format has been singular. The only other way is doing it by themselves without the agent. That is not democracy. That is anarchy, the other format for the process of governance. It also means there is only one form of governance—by the people who constitute the formal system. People governed people including themselves since time immemorial; people will govern people in time yet to be in memory—that could be pretty long. And only people govern themselves. The human system has been following it since yore; it continues today. But there are two processes of governance by people, direct or through an agent. Direct process of governance appeared first (anarchy) and governance through the agent came later, much later, and held on firmly (democracy). Take it or leave it. . .

If one takes it. . . then direct means there is no agent. The agent is the government in different types. Governance through agent is applicable to all types of governments. Such governments stay for longer period than when people rule themselves, directly. The form of governance when people rule people through an agent in this study is reiterated democratic, whereas the other governance where people rule themselves is called anarchy. Anarchy is nothing to worry about seriously. There is nothing frightening about it. It is not the end of the world. That is how the early humans governed for a very long time. That is until agents came to the scene.²¹ This deduction is to avoid any new terms coming into expression in a study where the future of governance is examined. This is to prepare the field. But what one needs to understand here is that in any process of governance there will be people for and against it. Whether for or against the government or governance, there will be people involved or indifferent to governance and, thereby, allow the process by acceptance or nonacceptance. Indifference as well as nonacceptance is also involvement of people for this study.

²¹ This is an interesting point in evolution. This could be deducted to life forms transforming into separate genders long-long ago.

In the traditional mold of nations, government, and governance, democracy is said to be not only different from others, but also considered to be the most modern and desirable. This is what is challenged, sorry examined here to avoid semantic dissonance and associated misgivings.

A responsible and scholarly friend in a casual discourse on serious governance once commented to the author that the rule and form of governance were about preferences. It was all about what suited one better, he said. He should know; he had the erudition to comment on it. He was not from a “democracy” as the way it has been seen and defined as people’s rule or majority rule for or by the people. He would certainly justify his type of rule or governance as an act of rationalization, justifying the subject matter against the global perception. He could; he had the authority being a responsible citizen of his country. His intention was not to offend the author who belonged to an electoral democracy as it is called. The author agrees with him not exclusively for the same reason. He was right in his argument. His statement showed the government and governance in his country had his approval as a citizen. This is where the idea of governance clashes with democracy as an idea. The latter term is a farce if not an idealistic mirage. It has to be mentioned now, at this stage, if future of human well-being is the object of examination.

But, what if democracy is taken as the only form of governance the human systems practiced since the beginning replacing the original self-rule by anarchy? There will be scholarly objections. They are acceptable. To avoid semantic dissonance, democracy for this argument is defined as the rule of the people other than anarchy, of their nation, where a nation is the largest human system post 1648 that is definable for governance.²² Can one say democracy is the umbrella form of governance turned into many divisions like the unitary World Ocean divided into named segments for administrative convenience? Yes, that is what this study looks at while examining governments as parts of agent democracy. One of the parts or types of governance is democracy as defined and known today. In fact, that is the argument in this study, where democracy is taken as the only form of governance possible to humans leveraging on the point that it is ultimately the people who rule themselves whether it is anarchy or orderly governance of unattainable perfection whatever may be the type of governance is called. Anarchy in a human system is order with maximum disorder within or when the order is zero or chaotic.²³ It helps to compare governance in varying degrees or levels, though may lack the consent of all. Maximum disorder is the state just before the warp through which the system transforms to another caused by the disorder in it. The time warp at the moment of death in the case of an individual is the maximum entropy moment which in terms of governance could be the instance of anarchy. In this situation, every form of governance is democracy if democracy is peoples’ rule by any means where the people give consent in different ways of submission to the rule. Therefore, democracy is not different but is self-rule with permission to be ruled by the chosen or

²² Here, it is reiterated that a system will have a definite boundary.

²³ Chaos too has order within. Open a common water tap at different turns and see.

consented competence in varying degrees of quantum wellness including zero well-being. Hence, a democratic form is the overall form of human governance with varying degrees of submissiveness, because it is reiterated that no governance is possible without human consent. Therefore, the study of governance in future is the study of democracy's changing shades, not democracy by itself since democracy here is a common name for all kinds of governments. In any type of democracy, there is admission of people or members of the system by approval and acceptance. It could be under absoluteness, submissiveness, coerciveness, casualness, oppressiveness, mutinous, or under any other form of acceptance. These viewpoints when put across in a major seminar²⁴ on developing democracy by the author, the audiences were divided. But the division was into two and not more. The division into two is another form of acceptance. Yes or no is the statement that proves the "existence" of the prime inquiry.

Belief in democracy as it is today is necessary to debate on governance; but the present theory of democracy needs to be reengineered to be acceptable for the study in governance by national security proposed in this study. That is what is done in the flanking paragraphs where first it is discussed as separate and then as human consent that exists in all forms of governance as a pervading factor. This may cause some problems for the voice of deliberations echoing all over human congregations on democracy and democratic reforms.

When the world celebrates International Democracy Day on a particular date (05 September), it is evident that the concept is one of the types of government, highlighted and argued (by some) as the most preferred one. Democracy is taken for granted as one of the types of governmental systems and not the only form as spelt out here in a reductionist manner for the purpose of placing the arguments in their analysis for the future. The macro format of government and governance is all about taking care of self as an individual and a member of a defined group to maintain well-being in a socially activated dynamic system. It has to be done through governance. The choice is to do it with or without an agent called the government, the name doesn't matter.

Democracy is projected by a section of society as the best and desired type of government all around the world among nations. There is another section that doesn't support this view. Both are wrong under the semantic dissonance of the term. Within this concept, democracy is a system of governance where people elect or choose their "own" government under franchise given by constitution, in whatever form it may be. No constitution is eternal. None of the countries that have a different regime will agree with the view that democracy as seen here is the best form of government. A friend's view has been already quoted. "Our form suits us," he said. Many such countries are powerful and doing fine compared to the so-called democracies. So where does the world stand? The world stands in two different parts, spinning around an imaginary axis of power and factors of power. It is always

²⁴National seminar on "Democracy decentralisation and political participation" at Government Brennen College, Thalassery. 15-16 February 2019.

bipolar with a sense of competitive mindset in governance. Within the ambit of this spin, people have to govern themselves either direct or through a government.

There are many definitions for democracy as one of the types of national governance. One of them is “democracy is a system of government by the whole population or all the eligible members of a state, typically through elected representatives.” It is substituted by a short definition stating “democracy is control of an organization or group by the majority of its members.” The latter is more interesting, if it is a majority rule. Those who are not part of the rule will also be there as subjects. In fact, it is exactly what has been happening since the beginning of human system governance where more powerful ruled the less powerful. Power follows law of physics; it flows in power gradient. It is visible in governance. That is why a state is more powerful than its people. State won’t exist if and when its people become more powerful. That is the reason for the statement in this study that every type of government is democratic and can be visualized in that manner for analyzing governance and its shades that will spread in an evolution inkblot.

As explained, this study takes a detour from the principle of democracy as one of the forms of governance to the only form that people are used to in governing human systems. It considers that every form that is used for governance of a human system or every approach that is adopted to govern has traces of peoples’ participation, taken as a sign of democracy ingredient. It invariably means peoples’ involvement in it. Every form of governance has its shade of conflicts which is inherent to it. It is the indicator of peoples’ participation in governance. This way, the study proceeds on democracy and its shades since the beginning of governance as a group and collective activity in a human system to share the competence in providing well-being to the members. But prior to that, a look at the present and accepted form of governance by democracy as one of the methods is warranted to carry out deductive exploration visualizing the future.

An interesting query that often rings around, more so in media circles, is about the ability of democracy as an exclusive form of governance to deliver. “Can democracy deliver?” is also the hidden pointer in the statement of author’s friend stated earlier. For him, his form of government delivered more than democracy, the author’s form of governance. Another vital question is, “can people handle democracy?” These questions are interestingly genuine. They can be examined later when democracy is visualized as a part of every type of governance including the so-called democratic format. There is diminishing satisfaction in democratic forms of governance according to some political opinion.²⁵ A survey in 2020 of the Centre for Future of Democracy shows democracy is in a state of malaise all over the global human system. This statement is a big giver on the conceptualization of democracy as an exclusive form of governance. If considered as a part of any form of governance, it is not valid. According to the find, the share of people who are dissatisfied by

²⁵Sahasrabudhe, V. Agenda for political reforms. *The New Indian Express*. Kozhikode. 15 September 2020. p.6

democracy (as a type) has risen from 47.9 per cent to 57.5 percent.²⁶ It is a kind of democratic discontent. This shows that democracy as an exclusive system of governance has not been able to achieve the true and enduring mandate of the people. It has not been able to make a significant difference in the lives of people. This state also brings out a question whether the pillars of democracy—freedom, human rights, liberty, and equality (add more), can be supported by democracy better than other forms of governments. It shows author's friend's argument was valid. Ultimately, it all leads to the desire that those who support democracy would like to show that it is better than other forms in providing well-being. But it doesn't seem to be clear and present. Nor any other form. If not, well-being and associated issues wouldn't have been there as if in a utopian dream.

So in a world where no one seems to be comfortable with any form of governance as the desired one, the political thinkers have multiple advices to provide. Some of them are contradictory. In all these arguments, scholars consider democracy as an exclusive and modern form. Most among them talk about political parties, parliament, and media as the key points. But a different perspective on these three institutions shows a big negation of the purpose of governance as providing well-being. Political parties are interested and vying with each other to garner and accumulate power by any which means to carry on subjugating others. Parliament becomes the arena for the political gladiators in traditional dress or wearing what in vogue. They echo their differences in war of the words sometimes leading to war of hands with fisticuffs and push and pulls. These parliament punch-ups, though laughable, are hilarious dissipation of political lasciviousness and incompetence of governance. It is often visible in electoral democracy as others may not provide such opportunity. So far, there was no war in a parliament using weapons as extension of hands and legs, though some of the members break furniture and whatever they can put their hands on recalling primitiveness of political agents. The reasons for absence of killer weapons may be that they are banned for security reasons. Interestingly, in many parliaments the members are hardly seen as they remain absent most of the time. The third key factor is the media. Media in governance amplifies the cacophony of the parliament in a way their purpose demands. It is noise for them, often taking sides with political parties as they assess them. An interesting fact here, according to these observations, is that political parties, parliament, and media are in reality a unified combo of democratic menu where the differences are visible only in their names, but the activity projections are identical. This similarity percolates to the extreme factor in governance—people. They too follow what the politicians follow in the parliament in an opinionated way, sometimes using extended weapons other than anatomical parts in democracy. Here, the media can be taken as the arena of political parties and parliament as the arena of the elected representatives that again points toward political parties. So, under this pretext, the idea of democracy remains in establishing political parties according to belief system-originated ideologies or objectives that are centralized and regimented. No one of them leads to

²⁶Ibid.

governance in any special manner. In these three cardinal entities postulated for democracy, people are not included. People are the end stakeholders for well-being. The politicians are also included in people. Consideration of well-being is for the people—not people as politicians or political parties. Therefore, people become an integral part of democracy and rest of the three cardinal points—politics, parliament, and media that become the route to well-being if processed together. Therefore, the control should remain all the time with people if governance has to succeed. That also means the accountability for the well-being of people lies with people in a democracy if seen separate from other forms. Ultimately, it is the people who are accountable for well-being, not the government who acts as their agents. This is where the importance of people comes in governance. People are the targets for the end objective in NS_{max} —well-being. It has to be people providing it collectively to them. Hence, the maximization of national security of a country depends entirely on people who are the government in every form of government, whether proactive or submissive.

This statement leads to an interesting find that it is not the form of government that matters, but the people if the objective is well-being in collective environment. The most difficult part in the confusing dissonance is not the complexity of government and governance, but the distortions the terms have acquired in the human system—it has been pretty long that humans were governing themselves, long enough to lose the way (Box 33.2).

Box 33.2: National Security, Government, Governance, Democracy and Anarchy

National security as a concept is about the measureable well-being of the people of a nation achieved through governance. A government is the agent of the people that help them to live and thrive together as cooperative species by origin. Democracy is one form of the two forms of government comprising various other types of governments that acts as an agent of people to help them in governing themselves. Anarchy is the other form of government where people govern themselves directly without an agent. This is a hard task under conditioned behaviour but easy to assimilate if attempted.

33.9 Human Well-Being in National Security Perspective

Human well-being is measured by social scientists in differing perspectives. Each one of them is justified. They can be physical based on health conditions, emotional based on emotional aspects, or mental based on various other factors that impact the neural systems. Here, one may stop to recollect emotional aspects within the mental (neural) aspects, but is seen for convenience of explanation. There could also be economic well-being based on income and financial status and developmental well-being where people feel better in a planned city than in an isolated village where

might may turn out to be the right. There can be expectational well-being based on the belief that future will be bright and comfortable when the present sufferings pass through. There are many other expressions of well-being: career well-being, family well-being, social well-being and even spiritual well-being associated with belief system perspective where God or the associates will come for help when the need arises. Any perceived threat to any of such well-beings pricks the balloons of wellness.

There are varieties of colorful takeaways or giveaways in the basket of well-being that the customers can take and feel nice and comfortable. But the government can have only one item—well-being as the ultimate moving goal of national security—a single product that is too difficult to achieve. The government's attempt at the make-believe happens rather than make it if one can compare their manifestos and action outputs for periods of time. No government has ever succeeded in providing absolute well-being to its people. One of the reasons is that it cannot be achieved in a human system. It can only be maximized. But how maximum is maximization is difficult to arrive at. One can only move toward it. That is what the governments have to do. There are many governments seriously into it. The passage to well-being is the well-being in national security. That makes the process and the target both dynamic. Therefore, the ultimate future of well-being is the journey toward it. In that case, human well-being remains the same from the primitive life to the most advanced life humans are yet to reach, but for the perceptions transformed by time. The transformation's en-route will be different by the perception. The future of well-being therefore will be as appreciated through evolution in every faculty of life. That means the world tomorrow will be the same as today like a never-ending play under changed scripts and scenarios. This wholesome wellness of citizens is the ultimate moving goal of national security governance.

Well-being is seen as QOL associated with pleasant and happy feelings of the system members since ancient days. But well-being in national security is the overall experience or feeling of an individual sans overly interference from survival emotions that are natural to humans. The government has to focus on human needs for collective well-being of its citizens. The point that is highlighted here is that national security goal is based on the collective well-being of the human system that is governed for the present and future. It points out to the fact that it is not focused on individual well-being or restricted to particular time or group, but sustainable well-being with a futuristic perspective for all people. Well-being cannot be measured through any direct metrics. It has to be assessed from collective projection of the individuals and groups in the community, intuitively analyzed for the future with sufficient supporting arguments. Well-being in national security can be correlated with various factors appropriate to each geoentity, though the idea of well-being will be identical in every nation as human beings cannot be classified in their mental makeup based on nationalities. Countries differ substantially in their levels of well-being. Societies with higher well-being are those that are more economically developed, have effective governments with low levels of corruption, have high levels of trust, and can meet citizens' basic needs for food, health, and physical safety and security.

33.10 Summation

Well-being for individual humans will depend upon their personal make up within their differentiality at any given time. It is difficult to assess in the national parlance. However, for the nation as a whole as a human system, the collective well-being of the people can be measured against the identified metrics of national security index. The measure of well-being in this case is based on the singularity principle where all the humans are considered identical in their needs' assessment and the perceived security (wants) ambitions and aspirations. The singularity make up can provide the measure of well-being as a national security index. Well-being to that extent is the apparent security aligned with perceived security. Both involve the efforts of government in governing the people.

In this assessment, a government is the agent of the people who govern a human system, the nation in national security studies. This is considered democracy for two reasons: (1) there is involvement of people by acceptance and nonacceptance (denial) behavior in collective governance of both the government and their actions—the governance; and (2) democracy as a concept has been well-accepted since the time of the earliest change in governance in Athens (507 BCE) with the appointment of an agent to govern the people by the entire adult population (above 20 year of age) and called democracy different from the practice of people ruling themselves directly without an agent. For this purpose, the assumption is that governance before an agent is considered anarchy and is taken as a singular format with many types in it. Anarchy still can happen when people decide to rule themselves. The latest was in 1991 when Somalia was without a government, but in anarchy till 2012 when an interim government was created. This has to be understood clearly now to study the concept of national security and prospecting the idea of governance. Since then, democracy altered in many different ways as part of evolutions in governance unlike what some call revolutions, etc.

34.1 Introduction

At the end of this study and before capsuling it, national security is reiterated as a concept of human well-being in the overall dimension of life. It is about governing human activities and factoring their productive outputs in human well-being. It is an open-ended mission for the governments of each nation or geontology with the involvement of its people in different modes. A close look will reveal it happening since the beginning of human system collectives. If peoples' involvement in governance makes it a democracy according to various political and social studies, every form of government is a type of democracy of sorts as there is peoples' involvement in one way or the other, in different human formats—active, passive, direct indirect, participative, resistive, submissive, rebellious, inert, contra (value reduction), anteforce, and other forms. That should make every form of government, the agent of the people, democratic. That is the argument behind and for this study. But what is called democracy today gives a different perception to the other forms of governance¹—monarchy, autocracy, canonic, communist—which are actually within the

¹ See Paleri, P. (2008). *National security: imperatives and challenges*. Tata McGraw-Hill Publishing Company Ltd. p. 470–75.

form of human rule with people's involvement—democracy. So, every other –cracy et al. is brought under the much highlighted and praised D-cracy in vogue as a type which hasn't been able to achieve much in human well-being when one looks at the way governments struggle, fume, and fret under the load of governance (author). The human system may do better by finding new types of governance under the form of democracy where human participation is by active acceptance to govern together to maximize national security and exercise checks and balances. It takes time. It hasn't happened so far. It is still the vintage format today. Why do governments violate the same laws they make? Violation of law is a strident cry in stillness. Yes, the author finds every government is whining in agony in one way or the other as if it is governing for the first time. In this statement, government means all included as part of the entrusted agent. Whatever, there is a lot of humor in governance. That also is an indication of the shady problems of governance. A lot of people survive and sustain in political systems by sheer competence doing well for the systems they belong to. Some gets butted down by anteforces too. In spite of all, governing should be fun, frolic, and compelling; otherwise, there shouldn't have been such a mad rush and competition to become an agent of the people to govern them.

Democracy is not new; it is older than Caesar's fossils more than four centuries.² Hence, the exclusivity of democracy as a standalone type of modern governance is withheld in this study.³ Every form of governance through an agent is democracy. Direct governance, sans an agent, is anarchy for this study. If that is so and believed firmly, there is a chance of prospecting governance better if the goal is human well-being.

Where the people have reached today since the days of the Athenian rhapsody or the beginning of governance is called electoral democracy. Electoral is only the adjective. Democracy is still the same. Even if the term democracy is pointed out toward Athens (Athínai in Modern Greek) where it sprouted in one of those acid-less rains on a fine orgasmic evening, Sparta stood like a monolith around there for higher well-being, if freedom and education for women alone are factored into the assessment of people's well-being by intellectual advancement. In contrast, look at the condition of women, more advanced than men biologically, in many parts of the world. That means a time span of 2500 years is insignificant in intellectual evolution. Sparta was ruled by two kings with participation of people. But it was not democracy according to the Athenian ecstasy; it is by this book. There are two kings even today in an electoral democracy. This shows human intellectual limitations too. The other thing is that the two kings in one country were chased out by people like hounds after rabbits subsequently. That proves peoples' participation—people, people everywhere, some chasing and some being chased in governance. This statement is

²Gaius Julius Caesar (100 BC–44 BC) the general who led to the end of the Roman Empire around the rise of Roman Republic. In this study the date of democracy is taken as the Athenian democracy around 507 BC.

³This was mentioned in a debate in an address by the author in the seminar titled "Democracy: Decentralisation and Political Participation" organised by the government of Kerala, India at the Government Brennan College, Thalassery on 15–16 February 2019."

based on comments fermented in history. There could be errors in the hypothesis. The only other form of governance humans could so far think of was “anarchy” (Wow, it would taste great! Ask the warlords). Anarchy is governance by non-governance. There is no agent for the people. Anarchy is about people governing their recognized geoentity without the so-called agents, the governments. One of the recent examples was Somalia. The then Somalia Democratic Republic was in anarchic rule by the people (only) from 1991 to 2006. Somalia was a member of the United Nations (admitted on 20 September 1960) in all honor applicable to other members even during the rule by anarchy.⁴ This is the interesting point here that makes anarchy the other form different from democracy which is without a government but only people’s random participation. A transitional government met in February 2006 for the first time. That gave way to Federal Republic of Somalia, a lasting governance system with a constitution on 20 September 2012. The country is called Federal Republic of Somalia with a Constitution since 20 August 2012.

Every human system of collective governance included all kinds of people, not just those who supported governance by acceptance through agreements or disagreements to balance it. This will highlight the need for a deep change in governance and to stop priming the point of electoral democracy as the highest one and the only form of democracy. It is just another type of governance. Every type of governance should be considered equally as each of them is engaged in governance, ideally for a common goal—well-being of the people. The *consensus ad idem* has to focus on the national security goal for any type of government.

34.2 Imperfection

Present has to be imperfect for the future to be perfect in a continuing process. That, perhaps, is one of the prime finds of this study. That leads to the state of the world and expectations of national security stasis in the “present” for any generation. It means every output will be imperfect if it has to pass through the present. Future has to wait for perfection. Future is never attainable; that is why it is future. In the *Gita*, imperfection is the path toward perfection. That is applicable to human activities. Familiarity is achieved in an activity by repetitive progress or rather retakes in the language of movie making. That is how the humans are nerved for turning

⁴Major General of the Gendarmerie Jalle Mohamed Siad Barre (1910–1995) overthrew the president of the then Somali Republic in 1969 in a coup d’état. The military junta under Barre reconstituted the country as a single party Communist Marxist-Leninist state under the new name Somali Democratic Republic. Siad Barre’s military government fell in January 1991 and the country was in anarchic governance by people without a government till 2006. That was for 15 years. A transitional national government was established in 2006 that was succeeded by the Transitional Federal Government. Till then there was no central government in Somalia. Today the country is a Parliamentary Republic.

intelligence into intellect. When *Gita*⁵ says perfection comes out of imperfection, the observation is simple and direct. There is assurance that future will be perfect if seen through human intellect. But nature has different ways of eliminating and immunizing life for preparing for future perfectness. The trick about imperfection leading to perfection but never to absolute perfection lies in the concept of growth which is vital in governing a human system. That means it will do good for a government in that its activities are in a continuum for sustainable governance (Box 34.1).

Box 34.1: Growth Will Die If Activity Intervention Ends Permanently in the Sapien World

There is nothing called growth if there is an end. National security governance, if seen from the perspective of a never ending assembly line, should aim at making the sapien world thrive better and better as it evolves, irrespective of the constraints in the interventional governance. An activity in national governance is part of a continuum of action. The nation, state or any geoentity considered a nation in this study in the present will be imperfect, but will be naturally and ideally better as future unfolds. The last condition, making it better than before, is where center of gravity of national governance will be felt transiently dynamic. If not, decline and total chaos and collapse are certain.

Growth stops when action is complete. It is the actualization of potentiality. All that were potential become actualities at the end. That is what completion means. Now, there is nothing else to do but to leave. Imperfection means there is more still awaiting, much is going to happen. Therefore, a country that is imperfect has tremendous potential to grow. This is important when national security is assessed. The moment a country thinks it is perfect it will be on the decline, the third stage, the one before death (birth, growth, decline, and death). This is where transition takes place from one superpower to another. The former gives up ghost after finishing on the line as a superpower permanently. But it doesn't happen from one superstate to another. The other too remains as a superstate in parallel because both are still continuing. A contradiction can be felt here. This could be clarified by stating that the best transformation through imperfection a superpower can get could be by not stopping at the finishing line, but moving further into a superstate stasis and continue perpetually. There are quite a few potential candidates for superstate, but none yet on the pedestal (2021). No one has thought about it. It has to be done through governance. It is also not necessary for a state to become a superpower to become a superstate. This book doesn't define a superstate for now. There is no yardstick to measure a superpower. But a superstate can be measured by national security index. Superstate stasis is achieved through self-anointment and external affiliations of military and economic power.

⁵ *Srimad Bhagavad Gita*, the ancient Hindu scripture.

The state of a nation can be imperfectly low. It is fine, if governance is gaining headway. It is a sign of continuity in growth if the condition is not declining below the lower surge point. It has been mentioned earlier that the human system advances through governance in surges⁶—forward and backward motions that are natural to gain momentum. The lower point of the surge will keep moving ahead. The cause of worry is when the lower point moves further backward than the previous one. Governance can see and apply correction to it. Such backward slip, if continues, can lead to anarchy, the second form of governance by people directly without the agent. The focus of governance should be to gain headway for the nation toward national security maximization, not sternway.

So, being imperfect is not about lack of perfection. An Olduvai cave may seem imperfect and so is a Malibu mansion. That's the way life goes on providing more and more clarity to the law of invariance and further to the law of limitations. So, an Olduvai is as comfortable as the private life in a well-stacked up island property where an individual spends a million or more in the most expensive currency in a day. Both have their elements of imperfection. The only difference today is that the Olduvai and the million-a-day island mansion go side by side with the inhabitants going through more or less similar experiences under different emotional takeaways. Well, both pray, eat, drink, screw and sleep, and getup with aftertastes. So what is the difference? There is. The difference is in the individuals, not in the caves or mansions.

At any moment in time, there will be “present” and a look at it just before it passes through the warp (the *truti*⁷) or anything shortest (*paramanu*) or a yoctosecond and further short (the Plank's time⁸) that the human intellect can appreciate will look imperfect as a sure sign of future perfect because it warns the human intellect to lead to perfection. However, the largest time span *Mahakalpa*⁹ is beyond human imagination and thereby a chance to believe in perfection of an output.

The imperfectness of the present can be seen at the spike point with respect to time. At the moment (2021), the visible spike point in the global human stasis is the

⁶Though not directly relevant it is important to understand here that a surge is not a leap. Surge retains continuity for perfection through imperfection that increases in backward surge.

⁷According to Hindu scriptures a *truti* is referred to as a quarter of the time of falling of an eye lid. It is considered to be 29.6296 micro second. But less than a *truti* is also mentioned. It is called a *paramanu* which is equal to 60,750th of a second. <http://veda.wikidot.com/vedic-time-system#toc3>. Accessed 25 November 2019.

⁸Planck's constant (h) is the fundamental physical constant in quantum mechanics that was introduced by Max Planck (1858–1947) in 1900. Planck time is roughly 10^{-44} s. However, to date, the smallest time interval that was measured was 10^{-21} s, a zeptosecond. But yoctosecond beats it by further measure of a thousand as 10^{-24} . One Planck time is the time it would take a photon travelling at the speed of light to cross a distance equal to one Planck length.

⁹*Kalpa* is the day time of *Brahma*, the Hindu God of creation and two *kalpas* (*mahakalpa* where the second *kalpa* is the *pralaya*, the great floods) make a day and night of *Brahma* after which the creation repeats. The interesting aspect of *kalpa* is that there is no infinity in this calculation. That brings out the perception of endlessness of life. This also means imperfection is the acquired perfection at the particular moment in time.

C-19 pandemic. The spike is the point that outweighs every other gremlins of imperfection. Like the fight for power, terror, crimes, unsettled lives, corruption, pleasure, orgies of vulgarity, lascivious dissipations—all go through the warp only for others to come. At the same time, the developmental programmes can continue indefinitely as in the past where C-19 can be taken as any other constraint in the path of governance, if not a life accelerator or an agent of natural immunization.

In governance, imperfection is an interesting theory. At a particular time (can it be said fateful time?)¹⁰ about 3.26 billion years ago, an asteroid of approximately 37–38 kilometers (23–36 miles) wide struck the Earth. Years later, well, a lot of years later, around 65 million years or so back, another one about six miles in diameter struck near the Yucatan peninsula (present Mexico). In between and thereafter, the solid showers of rocks continued. They certainly would have been the sharpest spikes of the eonic periods while the planet was getting roasted like a brick in the kiln.

The world being a continuum as far as this study is considered will always be imperfect when taken stock of the present. It is a healthy sign if the imperfection of the day is lessened from the previous day. That is also one of the reasons that the author recommends addressing the humans of the twenty-first century and further as sapien humans, at least figuratively, the determined group of humans who will lead toward perfection through imperfection in many life times, one step at a time, a better one that too. It also means national security governance needs to be premised as a continuum and not a disrupted move forward in staccato fashion. In the looking glass of present imperfection, it is the C-19 pandemic of the day (2021) that will gather the attention of even an intelligent visitor from deep space.

34.3 C-19 in 2020 Avatar

On date, in the continuing present, the human world is naturally imperfect reeling under the viral disease, Covid 19, caused by a virus baptized as SARS-CoV-2. The virus came humming the theme song “mutate and survive” seemingly to stay or at least without intention to leave early. The intention of the virus is not clear even now (2021). Is it friendly, pathogenic, or commensal, and if so, on what kind of human bodies, etc. are not known. There are many mysteries associated with the virus that the bioscientists are engaged in unfolding. They will. The global human system depends on their respective governments in all situations that demand attention and concern. There is much ambiguity in the perception of the citizens and the grapevines originate from them. Unlike in the past pandemic periods, there is much resilience and determination beside seizing the opportunity. Some governments and world bodies are after the vaccines, and some are after those who are after the

¹⁰No. It was a natural incident on the day it occurred. The asteroid was not a threat under the study of national security. It will be, if it happens today.

vaccines. Some find fault and want to reject any vaccine out of uncertain information situation wholeheartedly as something that may save humans. Some are private and secretive; some are open. Many want to seize the opportunity to earn money not only through vaccines, but also on the daily covid mantras and deaths. Some complain about organ harvesting from the dead in the middle of covid deaths. Some bother; some don't. All are well. Certainly, the times have changed and law of invariance prevails as pathogenic viruses keep reappearing since 3000 BC, the earliest known time so far, though human reactions toward them differ. This was the least cryptic of all the pandemic times in the world, though bad and difficult. No, there is no contradiction.

The virus may be a slim customer¹¹ for many, but it doesn't care, as if it owns the space, time, and lives (human life in this case). The chicken that infects is culled. What would have a superior species done if humans got infected by a deadly pandemic bug? Yes, that is the silver lining on the cloud. Humans are lucky they have no superior species who would have culled them. But they are not able to take the attack of a much inferior life form, sorry nonlife form, the celebrity virus that was looking for a cell to get in and grow.

Life has to continue. It has been happening. Weak ones removed, strong ones spared, yet others strengthened to survive. What the world goes through is on a different track. That happens to all. There are no common lines or tracks except the natural track and relative tracks. Relative track is for people to follow or groups to follow. Natural track is real and consistent.

The biggest news in the present imperfect scenario (at the moment) is the pandemic and how it will continue for some more time. The scientists believe it is here for a long haul. By the end of 2021, the virus would have been a difficult tenant for about two and half years among the humans. The humans would have become less careful, complacent, and more acquainted with the mysterious virus. It would have become used to various normals in life style and behavior. The virus as it is now may continue to spread at low burn or may increase its appearance in human bodies more vigorously with equally counter immune bodies. This may be the result of the vaccines as well as immune generating antibodies of different portents and potencies. There could be news about the side effects in the application of vaccines. Some of them could be real and some mere exaggeration. But still people may die directly because of issues of morbidity. There may be some whose death may be attributed to virus even if the cause is different. That is how imperfection functions. There is hope, tremendous hope, among governments and practitioners which is the basic working ground for medical practitioners and scientists even in the modern day world. Siddhartha Mukherjee, medical practitioner and author, clarifies three laws of medicine which highlights (1) intuition is better than a weak test, (2) normals teach rules whereas outliers teach laws, and (3) there is no medical experiment without

¹¹Lim customer means unwanted guest. But in real sense it may be the way nature cleans up life systems periodically by taking off the weak and strengthening the strong to face future challenges for system continuity.

human bias.¹² This cannot be more correct and better explained than now at the time of imperfection caused by C-19. Medicine for Siddhartha Mukherjee is an uncertain science. It is.

34.4 Hanging Indents of Imperfection

The big question is did C-19 steal the show in the scenario of imperfection in the world in the twenties? It was the beginning of the third decade of the twenty first century when this study recommends *Homo sapiens-sapiens* to be sapien humans, a bit advanced in its forms of thinking and understanding about the need for sustainable human life as the end of the decade is expected to meet the sustainable development goals. There is only a decade to cross. Will Covid 19 clean up or lessen the imperfections in the haul of a decade? Or did the world treat C-19 just another imperfection in the mirror along with various other incidents equally squalid? Or is C-19 a normal thing which within the governing scenario of the day matches with the rest of the indents of imperfection?

For some, the corona virus is the key player in the twenties. Even a child knows it unlike in the past. Ever seen a virus becoming a killer celebrity? This should be the first time. AIDS was ugly and notorious. It was identified in 1983. It doesn't have an antidote even now. The impact of C-19 on the world economy is real. But good governance should be able to turn it along the V-curve swiftly. The pandemic also provided economic opportunities, especially in the cyber terrain. This shows the importance of terrain specificity in national security. More the terrains, less will be the economic isolation in panic situations. This is a notable point. Difficulties caused by a situation in human well-being in one terrain could be used to strengthen the faculties of another and take advantage. C-19 was a problem over the land and air. It made humans more dependent on cyber and to some extent on the ocean for energy security by managing oil supply chains, though there were other problems. This is an area that needs further research. In the past whenever pandemic struck a la C-19, there were no similar opportunities. Therefore, the virus cannot take the blame. It has strengthened human passage into other terrains and advanced human knowledge for the better. Majority of people think the virus has changed their lives. But there are others including the author who believes that the virus has only altered life which is a normal in human system existence. It is for the governments to find interventions to achieve the objective of governance by making situational alterations and additions in the format of governance.

¹² Mukherjee, S. (2015). *The laws of medicine: field notes from an uncertain science*. TED Books. The laws are (1) A strong intuition is much more powerful than a weak test, (2) "Normals" teach us rules; "outliers" teach us laws and (3) For every perfect medical experiment, there is a perfect human bias.

The people too are not complaining, but for political reasons and compulsions. The religious axis is comparatively quite in complaints in spite of many restrictions imposed in meetings with the divine and the absolute unless some specific section observes partisan policies in governance. God has no complaint. Most often, people followed government directives under self-discipline. According to Pew Research Institute, a good number of citizens, especially in countries such as Australia, Canada, Denmark, Germany, the Netherlands, South Korea, United Kingdom, and United States, feel their governments have done a good job.¹³ India too feels it, but the opposition cannot blindly agree with the government. That is their job. Of course, statistically researched results may have limitations of accuracy. Opinions of individual citizens can not only vary, but also change subsequently. In addition, the pandemic is still there and shining in 2021. It is early to conclude on it.

Geostrategically, the world still differs in opinions. There wasn't any war, though the talks on war and waving the flags and ensigns to up the ante existed among many nations globally. The international relations of China were encouraging for the country in every respect, though there were wedges thrown in between China and many nations. There are group formations on Chinese geostrategic context which also exists among potential powers of the future. China has developed on fast track geostrategically, economically, and technologically amazing the world by projections of power and affluence. It is accepted by the global community that China is at the moment the greatest economic power of the world. It is not based on the usual straight line assessment, but the way China has been able to penetrate the world and the minds of people by sheer projections, clout, and propaganda. China can become a superpower on the planet and replace another on pole of power axis. China has made enviable advancements in science and technology, especially in nuclear fusion for energy generation, cyber systems and security, and space technology. In the meantime, the US government has been able to divert the blame for the pandemic considerably on China which most of the Americans too believe, but have not taken seriously. Geostrategic pundits noticed souring relations between China and the United States.

International cooperation is highly imperfect. It could be attributed to the pandemic restrictions. People want international cooperation to be enhanced even if it means making compromise. The 2020 Nagorno-Karabakh conflicts were an aberration of the year assessed for the present.¹⁴ But the settlement showed waning of such incidents gradually. The general feeling among people of nations is that their countries should follow their own national interests. It is natural when the countries think collectively as a system in a more insular manner. Insularity is traditional. Opposite to insularity is openness. Openness can contribute more to human

¹³<https://www.pewresearch.org/fact-tank/2020/09/23/how-people-in-14-countries-view-the-state-of-the-world-in2020/>. Accessed 20 October 2020.

¹⁴The 2020 Nagorno-Karabakh armed conflict (Operation Iron Fist by Azerbaijan) was between Azerbaijan, supported by Turkey, and the self-proclaimed Republic of Artsakh together with Armenia that took place in the disputed region of Nagorno-Karabakh and surrounding territories.

well-being globally. Insularism can cause issues in well-being. This subject needs detailed study. But the world is expected to move from insularity to openness and wider perspectives as time passes on as a natural trend. The gradients are visible in the present imperfection. The world will move on together. This unison is also one of the achievements of C-19.

Competition is a must for survival for the better. The world prefers proactive and supportive competition. It is a hard sell or rather too early to harp on. Humans need time to decondition from the conditioned behavior and also to recondition into new and desired, if at all they can. This is where governments have to get their people deconditioned from erstwhile negatives. It is a task for governments to carry on under prevailing imperfections.

Anxieties of climate change loom large in spite of efforts to control them and the much talked about positive impact of C-19 on the environment. No, it didn't happen. The world became hotter in 2020. That is a serious imperfection. The world was heading to temperature rise despite C-19 lockdowns according to UN. The annual Emissions Gap Report 2020 of the United Nations Environment Programme (UNEP) revealed that despite a dip in the carbon dioxide emissions because of the C-19 protocols, the world was still heading for a temperature rise in excess of three degree Celsius in the second century. The goal of the Paris Agreement (2016) was to hold it at two degrees Celsius. The UNEP has urged governments to invest in climate action as part of green pandemic recovery and solidify emerging net-zero commitments with strengthened pledges at the next climate meeting (November 2021). It is important to bring emissions to levels broadly consistent with the two degrees Celsius goal. It is the prevailing imperfection in climate change that the UNEP thinks can be rectified for now.¹⁵

Another concern for countries is cyber attacks external to them. The sharp fall of economy and loss of jobs (there are also creation of new jobs) were common to all countries. Opposition politics played sharply in many countries against the ruling politico on the fall of economy attributing the blame to the respective governments. But in a human system, the holder of authority, the government in a nation has to bear the grunts and brunts through accountability for any imperfection including showing the edge to the future from the perspective of citizens.

Hope is an interesting aspect of imperfection. It can be used as a sign to measure well-being, though it can't be unified in yes or no condition as it vacillates. Opposite to hope is anxiety. Though anxiety has not gripped the nations, hope has reduced to white hope. That is hopelessness with hope of things to become better. Dark hope is hopelessness under depression. This feeling in people sans deep anxiety is a sign of the feeling that things will become better. The anxiety level around the world is low and people have faith in most of the governments, though expressions will be axially biased.

¹⁵“Despite COVID-19 lockdowns, world heads to temperature rise: UN report.” <https://www.indiatvnews.com/news/world/despite-covid-19-lockdowns-world-heads-to-temperature-rise-says-un-report-670390>. Accessed 13 December 2020.

United States has been able to wash off its negative appreciation retained by many nations after the Iraq war considerably by this time. Internally in the nation, there is a deficit in ethnic security in national governance. It is seemingly temporary and a change in government may bring the balance back, though it hasn't made much a dent in quantum national security governance. Interestingly, the scenario focuses more on the nature of governance than who governs a nation which indicates world is no more dependent on a specific leader as the only hope for a country. It is the nature of collective governance that matters. This is a healthy nature and very apt to GBNS. Governance matters, not the specific individuals who govern. The world is moving away from individual and personal leadership to group and collective leadership. In the Pew research quoted elsewhere, it is seen that some of the prominent leaders of the world have been considered low in public opinion.

In the overall, the concern for countries varies among the identified imperfection. For some, it may be pandemic; for others, it may be cyber attack or climate change. This also confirms the view of the countries that national interests should be given priority. It is true with respect to national security. But it is time geostrategic security is given way by governance based on insularity mindset. That could help the world to be viewed with a sense of openness.

Though imperfection prevails, situation and surge of human well-being were seemingly positive in the present imperfection. It is encouraging for a better world as it should be. This also shows nations are governing for a better life which in turn is an assurance for the success of UN SDGs and a positive pointer toward its continuation in some other format by transfer to new. The continuance will be known only after some more time. Yes, the world is going to be a better place to live and the title sapiens for *Homo sapiens-sapiens* from now on in their life style governance is a good trend psychologically and suggestively. It is time for the humans, sorry, modern sapien humans to change their proprioception and breathe well-being.

34.5 Carrying Legacies Forward

While detailing the imperfection in the previous sections of this chapter, the year taken was 2020. It is considered a span of the moving present. Assessment of a year, especially when it was unfolding, is fine for a quick look at imperfection. The imperfection that continues into the future keeps the present going for the visualizer or the intervener. No one can step into the future or step back into the past. There are limitations. The present can accompany anyone as a shadow all the time. But then, the world at any time in the present cannot be something that started now. Now, the present carries the legacies of the present. The first and foremost of them is the DNA. It was discussed in another chapter.

Every issue in today's world will have its legacy. Some of them will be visible and sentient to the thoughts of the investigator. Some of them caught in the web of time, extending backwards in history (historical time), legend (legendary time), and

myth (mythical time) in that order, are mostly distorted in varying measures based on the time that moved irreversibly backward.

The world is cold that those in the tropics may not feel. It was cold enough to hold the water crystals in ice form. Humans in general may not be aware that the Earth has been alternating between long ice ages and shorter interglacial periods for around 2.6 million years or so. It has been happening for the last million years or so roughly every 100,000 years—around 90,000 years of ice age followed by a roughly 10,000 year interglacial warm period. The current interglacial period commenced around 11,700 years back after a glacial period of about 90,000 years for the last 2.6 million or so years. What does this mean? It means the next ice age is nearby. Can it answer the rise in global temperature as if something cyclically programmed and not fossil fuel burning? If so, the signs already there are that humans do mistake for their own inducements. Or maximum it could be default cum inducements. Aren't the humans too insignificant in bringing a change to the life systems and the physical system they are in?

34.6 And, Hence Global Governance

There are many among the public who argue for global security and global governance. But the concept if accepted will be different from the national security principles advocated here. It has to be studied in detail and separately from the national security concept. It will take time, a very long time to shape up. Till then, global governance will be as it goes with reference to situations and demand-based objectives. Presently, global governance is only about the commitments the heads of states and other political authorities make on paper remaining under the C-19 masks. They are subject to many changes as time passes on. Nongovernmental organisations (NGO) figure considerably in matters of the present day global governance. But many of them are treated as slim customers who support economic, religious, political, and other interests of clients they are directly or indirectly working for. Many of them are considered engaged in covert and subversive activities in the host countries or communities they work in. NGOs come in different shapes and characteristics. There are many who are engaged across borders of various nations with huge funds. NGOs certainly are not the intent of global security. Global security is a matter of global governance and not private intervention standing separate from governments in the pretext of serving people. But it is difficult to identify the genuine, though the governments will have ways of recognizing. It is the common person who will be hoodwinked by nefarious NGOs whether it is a fisher, indigenous dweller, or a simple educationist. Some of the NGOs involved in the name of environment are also earned the names of environmental terrorists. Interestingly, there are many NGOs of repute engaged in humanitarian efforts with the support of international organisations.

Worldwide corporate social responsibility (CSR) is another activity that the corporates can engage in, which could be extended to terrains other than land in

course of time. CSR could be used in the ocean as corporate ocean responsibility (COR) in terms of law enforcement and environment and human services such as search and rescue of people at sea. This will bring good order and discipline in the ocean.¹⁶

There are many actors and stakeholders in global governance. The whole world becomes the stage when the concept of global security is consolidated. But the problem is whether it is possible against the reflections of ethnic security principles where people stand separate from each other in one way or another. It will become a problem when demographic density increases by mere size of it. In another perspective, it looks possible when the need for such commitments among stakeholders is desired. It can happen in the sapien world. So, the possibility is that the world may strike a midpoint between global security and national security. In this scenario, it is possible for international organisations including the UN and international laws to undergo major changes for the better from imperfection to filtered imperfection. The parties to it will be naturally the national governments along with the recognized and responsible NGOs, corporates, transnational actors and agencies, and so on. Global governance of such kind will anyway require agreements, norms, regulations, law and treaties, institutions, and various others. The rationale is obvious: there is a lot for a nation to do globally and internationally under the geostrategic context. This will also be an extension of geostrategic security, the element of national security. Cooperation under multilateralism thus can become a necessary precondition to making progress on the world's problems.

35.1 Introduction

At the end, it is about packing up to revisit at the appropriate time in future. It could be long, very long. There are a few questions to answer prior to calling finals. The scholars and experts may work on them as convenient. National security is citizens' subject. Every citizen has a stake in it. Therefore, it will be apposite that the opinion and critical annotations of each and every individual find a place in the continuing research on the subject.

The ideations in this book are exclusively for defining the concept of national security as envisaged by the author based on his studies on prospecting national governance and human well-being where the concept of national security is as defined in this study in a human system environment that is limited to the natural

frequency of evolution sheltered under the law of invariance inconspicuously at the moment of happening. The points identified in this study, therefore, are meant primarily for attempting in national governance unless found useful elsewhere in smaller human systems by those who are concerned about their governance. To that extent, the identified points differ from ideas elsewhere in the social systems. Any disagreement in this study, therefore, is agreeable to the author.

In the odyssey of life, the neural system plays a larger than life role in humans as it controls the intellectual capacity, the survival tool, among others. The neural system, medically known as the nervous system comprising the central and peripheral subsystems, spreads out to the entire dimensions of the body.¹ The system is designed, programmed, and constantly upgraded by evolution to devise survival strategies for life. Yes, the human body is wired very intelligently, adroitly, and sinuously in relation to other multicellular life forms. One of the survival strategies, seemingly the earliest of all, was to huddle together against a common threat—getting organized into formal and informal groups. They did it, and did it extremely well, even shedding blood to hang on and keep human life going with all the problems associated with existential sustainability. It looks odd that the purpose of human life is to continue life, not one's own. The survival instinct is etched in the genes of all living things, continuously modified by the supporting environment and carried forward in a chain that will (perhaps) never end. They will reach wherever life sustaining conditions exist or can be made.

35.2 Sapien World and National Security

Sapiens for this study are the modern humans of the biological species: *Homo sapiens-sapiens*² leveraged on the twenty-first century who have to lead the survival spirit of life, especially of the species, by avoiding chances of a total constructive loss³ any time in future. Well, the dinosaurs couldn't do it for obvious reasons. Many unknown species would have met the same fate of total annihilation never to refresh and return. But this study firmly believes humans will continue. Then, why not as

¹For the purpose of this study the neural system is a socio-technical modification of the term nervous system, which is a complex medical term and field of study meant for medical and scientific professionals, scholars and researchers.

²*Homo sapiens-sapiens* is the name given to human species if considered a subspecies of a larger group. This name is stuck with humans among the scientists and public users but needs a change in the governance mode that too for national security governance. Humans need to discard all the mental inhibitors to face limitations in evolution. A change to an exclusive species—sapien as used here, though in suggestive mode may help to beat the law of invariance without damaging the inkblot of evolution.

³Total constructive loss is borrowed from a legal term in insurance where the recovery of the lost will be more expensive than rebuilding or reengineering a new one. It means life has to continue with alternates instead of holding on to the old.

sapien humans, a bit modern in thinking and spirit, determined to live well in a new avatar by shedding the tag of *Homo sapien-sapien*, as a transformed citizen species of the new world with brimming self-esteem and expectations of well-being. Humans need to push themselves a few notches up ahead along the line of evolution, shedding the slow pace at which their intellectual growth is moving. Humans have reached the stage of being sapien, evolved and determined to face the challenges of the future with the new found esteem and determination. If not, at least believe it. The author feels so.

35.2.1 Unitary Civilization

Human system is seen here as grown together all over the planet where humans existed and still exist, increasing in system membership by birth. It makes the civilization unitary for this study, where civilization is seen absolute as a system with clashes and conflicts within, not between. The individual members live and die within the unitary civilization developing differentially within it at different positions along the line of advance on the time track as a whole. At the same time, they retain their biosingularity of oneness relative to life. This is a peculiarity of the sapiens (unless the author receives a dissent note from any of the other life forms, there is no need to investigate, being the author's view). The assumption of the unitary civilization in national security study is for considering the human system all together with individuals at different stages of intellectual development with aspirations and perceptions appropriate to it. Gradually, in course of civilization, enhancing unitarily as if shaped in a worm tunnel, nation states emerged as the strongest and largest of all human groups statically positioned at different geolocations. The process was governed by the laws of nature.

Though many scholars find the world a human settlement of various civilizations at a given time, there seems to be reasons to believe that the entire humanity was part of a solitary civilization at diverse stages of development. It is continuing under the concept of unitary civilization as mentioned. The stages otherwise present the impression that there are many civilizations. The idea of multi-civilizations in a single world at a given time is more acceptable for people when viewed from their own pedestals of security perception. There is belief that highly developed settlements truncated at times for unrecorded reasons (disorder maximization). In spite of extinction of certain groups even at advanced stages of affluence, humankind multiplied and developed under powerful life-sustaining forces. It gives credibility to human capability to adapt to the laws of life-sustaining forces on earth and to the consequences of their violation. Civilization is the overall outlook of human group activity at different stages in different shades and a function of time. It is not about affluence. Human society will always remain a mix of affluent and less privileged people at different times at different levels. The unitary civilization cannot collapse. It is live and vibrant. A stage will end when disorder within it is maximized. Containing the "disorder within" is important to retain "group security." Another

lesson is that human beings possess amazing ability to survive under their seemingly weak body projections. No disaster or calamity so far in the world has been able to eliminate the humans or reduce them to the status of endangered species. They are multiplying against all odds.

Today, land grabbing by colonization or aggression is almost history and nations are free within the framework of independent constitutions or similar statutes. There is no more free land for occupation. The entire world is partitioned as if in a grand old joint family, with simmering disputes across most of the borders. The disputes are not common across national borders alone, but also within nations among the internal partitions. The people of the world are not free. Domination of the powerless by the powerful is persistent. The attempts of domination and the stages of development of humans also give the impression of multi-civilizations. The continuing clashes between the dominant and the dominated, or the aggressor and the vanquished also project the impressions of clashing civilizations. In reality, it is not so. Such differences thrust upon the nation states an informal and vacillating hierarchical order as reflections of the human societal systems. The world has been truly global in concept with respect to human systems at all times. Its societies cannot be treated differently under any time frame. Therefore, what is identified, as different civilizations, are best treated as the subsystems of a grand unitary civilization. For this reason, the clashes are within the civilizations, not between civilizations. It helps in problem solving for national security. The stages of human development leave the trails of survival techniques. It is prudent to follow the lessons learnt from the passage through these trails. They are long, winding, and continuous. Within these confinements, one has to identify and maximize security and through it the well-being in life.

35.2.2 *Laws of Nature*

Laws of nature, as mentioned here, are exclusive to this study that explains human well-being along a different tack. These laws need not be applicable anywhere else. The purpose of introducing these laws is to guide the study of national security concept for prospecting governance for human well-being with respect to a nation, where the nation is a geopolitical and geostrategic entity that is governable. The concept of national security is meant for national governance. It need not be applicable to lesser human systems. It is possible to enlarge or topologically extend it for global security, if and when such demand arises. Such demand is not likely to arise for a very long time. But, it is possible to transfer these ideas to other organisation including family systems and corporations, if studied further.

Presently, the study identifies two specific laws of nature in national security governance: law of invariance and law of limitations.

35.2.2.1 Law of Invariance

Law of invariance states it is not easy to perceive a change with respect to well-being in a human system at the moment of time warp of the change. A change will be visible only after a particular time lapse. This is important to know at the time of decision making and assessment of impacts of a decision normally or counterfactually. So, according to law of invariance what one sees in future will have considerable similarities with the past.

The law of invariance states that, *“the changes in the core behaviour of a human system, while a reality, is too negligible to notice and, therefore, for a psychosomatic system application relative to humans, it is sufficient to presume the model applicable today would be constant in time whether it is past or future,”* (Chap. 1). Under the law of invariance, what human experiences in a life span within the human system will be more or less similar to what someone before would have faced and experienced. Hence, it can be concluded that the future too could be similar in experience.

35.2.2.2 Law of Limitations

Law of limitations not only controls the “edge” humans can reach, but also is the cause of imperfection in any activity attempt. It originates from the fact that the life systems will not be able to look beyond what is sustaining life at the maximum. Imperfection leads to perfection in human attempts not in leaps and bounds on a kangaroo track, or straight line process, but in surging process of forward and backward motion. This motion should not be mistaken for a pendulum or sway. Surging, here, is moving forward and backward in motion, but gaining distance in each move forward, which need not be equal to the move forward as it retreats to a lesser degree before the next move. The laws also limit the intellectual prowess. Under the law of limitations, human capacity will always be limited to the extent of necessity in a surging fore and aft dynamics. It is the law of limitations that forces humans to fly with superman and climb the buildings from outside using (imagine!) a spider web string. Fantasies are triggered in human minds by law of limitations in one’s capacity or, rather, fantasies provide the proof for understanding the law of limitations. Humans negotiate the law of limitations through fantasies beside other supporting activities to break into perceived security. Humans can’t fly by flapping hands when they don’t have to do it for survival. Still if they want, they can use their survival tool to make an aeroplane, a survival pod that can fly through a terrain that they are not used to for living.

35.2.3 *Ultimately Nations—For Now*

Human settlements enlarged and became sovereign nations. Nations didn't move; people moved across nations. It is interesting in many counts.⁴ Nations further enlarged or shrunk in size by macronization or micronization, respectively. The continuum broke in many situations like breaches in ant columns. But, people remained and continued either shifting to new geolocations or remaining static where they were under new names and nationality. Nations did not vanish into thin air or disappeared like tiny oceanic islets underwater. Names changed; sovereignty got redefined. Geoproperty regimes changed. But none of these affected the forward movement of unitary civilization. The traits of globalization in human perception and activities are evidences.

The underlying principle of this study is to visualize human system as a whole with individuals developing together in varying stages under obvious differences within a unitary civilization of humanhood. In this posit, the nation is locational attire. The idea of nation states became a reality and caught up with times providing identities of their own to chosen human systems in the great club of the world of nations. The process continues and is likely to be extended to the future. The changes are on at every moment in the time warp invisible to humans under the law of invariance essential for balancing the existence. Micronization and macronization of nation states are expected to be a continuing trend, though chances of integration or merger of nation states will be remote and passé in course of time. This study does not propose disintegration as a term to explain the breakup of any nation. A nation needs to be valued as a distinct and dignified entity that holds human systems comprising people, the most advanced and dignified life form on the planet—the sapiens. No nation, therefore, should be visualized as lower to another under social and bioethics. It is time to treat humans and human systems with sapien dignity—the sapience. Beside, the opposite of disintegration doesn't go well for another nation's effort to invade a neighbor and grab land, as integration. A nation can be micronized when its land area diminishes or macronized if consensually enlarges.

Nations as human systems are independent holding bodies of human beings with self-esteem and dignity. It is important to understand it. There cannot be rogue nations or failed states. Treating nations under such terms is disrespectful on the part of the blame thrower in the sapien age. There can be rogue governments or leaders in authority who fail their nations. Here, nations are seen as macro human systems. This study treats nations as geopolitical and geostrategic entities that protect its people, hence more decisive and accountable than its people. Governance, therefore, needs to see the well-being of the nation, the entity, before people. The mariner's

⁴Not examined further. Recommend more studies on this concept sited here. Is it possible for nations move spatially like the way people move? The second question is, "Are people being pushed to a niche on the Planet that belong to them for reasons that is not similar to the other life forms?" Humans are the only life form that can get acclimatized for almost any place in the entire planet. Then why remain in a small hole called nations?

principle of “first the ship, then the people in it” is vital in the anatomy of a nation and its governance.

35.2.4 System Spin and Axes

Formal groups based on belief systems created and controlled geonities in the name of governance thousands of years before and thereafter lap dissolved into the idea of sovereign nation states, still retaining the traits of the past. Clash between two different sections of faith in a religion (Thirty Years War) within the unitary civilization of the human system was the basis for the European model of sovereign states in the world today. Belief systems dominate national thinking, though sovereign states paved the way for differentiability to take refuge in singularity within and between the human systems. There are religious protagonists who still dream of creating unitary worldwide religious nations of their own religious beliefs by unifying the people of the same faith and work toward the objective. God as “God, gods and no-god” controls the human system since the time people were wandering over the planet in their quest for survival. God is necessary even as no-God for humans to anchor their mental stasis, at least for now and some more time ahead. Religious belief system is much stronger and perceptually powerful than not only other belief systems, but also national feelings in general. Its need for a human system is different from the need for a nation. The religions tend to spread their flames in global conquering, whereas nations under political power attempt to find well-being by governance remaining in their comfort zones of national boundaries. The concepts of religion and nation are seriously asymmetrical, though in certain cases compatible and fused with each other. The asymmetry is hidden often oblivious to the protagonists themselves. This can be seen in a biomodel. The usage of the term religious war to depict some of the conflicts originates from this asymmetry.

So, naturally there has to be a binary system of social control. The binary axes of the human system are set on the power of the religious faith and the power of the political belief systems, in that order looking at the residual control of human systems. But the power that explicitly divides the nations today is political belief systems with deep shades of faith and belief assimilated in them. It is not known whether this shade in the political national system is spreading or withdrawing. It can be tested, and in all probability, it is waning through a hypothesis at the moment. But seemingly, the divisive power or separating force of sovereignty is more forceful relative to faith and belief so far. Still the feeling that religious belief system is stronger and thicker than the nation can leech into the human mind. Nation is more powerful than faith or belief system when it is about apparent security. The answer is that no stable nation can be created on religion or any other belief system. A nation is needed to govern belief systems. But it can't feel comfortable without dabbling and wading through perceived security. That is the catch. Otherwise, the nation will not sustain. Nation thereby is a tad bit more important in national security. That means

the nations are based on God, Gods, or no-God. There will be three different types of nations if such a divide comes with many subdivisions within. Even anarchic conditions have to be balanced axially. A burning plane crashes, not vanishes into the heavens after a religious terrorist attack. That is the reason why it is not likely that a balanced human system can turn topsy-turvy. This also answers why the Thirty Years War ended without any one winning or losing and remained for fighting in the future, if they so desire. Another reason is that religious inkblot model tends to spread into the entire human system without knowing it can be self-destructive. Religion cannot respect national feelings because it is relatively inferior in the apparent security context to the rule of governance than the perceived security governed rule of dictates and insularity. National security is apparent security-specific; belief system well-being is perceived security-specific. That is the difference. Only governments can handle it in national security governance. In all these explanations, the readers may have noticed that the word nationalism is not used by the author because it is quite archaic for explaining national security concept. National security is not nationalistic security in any respect. Nationalism causes semantic dissonance in governance by national security discussions.

For these reasons, the axes are concluded in the order of politics and religion (the prime belief system at the moment) below for academic explanation, though critically separating them is not only possible but also not advisable. Beside, the belief system axis came much later than political axis, though the latter has better holding in the theory of the evolution of nations. It is important to understand that the human system spins around a unitary axis which is integral to the binary axes explained below. It will remain so for years to come like two bodies buried in a single coffin as understood by one of the students of the author. The explanation below is of the coffin exhumed and opened for temporary break up for separate examination. It has to be repacked and shut thereafter.

35.2.4.1 Axis 1—Politics

Sovereign nations are designed and governed as per the ruling political ideology even if the constitution in many cases or the ideologies to that extent may claim the country belongs to particular religious belief system, but follows governance politically in the world of nations. Ultimately, the process that is on is the nation concept based on politics gaining power. The question whether a religion is larger than a nation can be answered in favor of nation from this finding, though there can be difficulties in accepting it. It is time one gets rid of the doublespeak in national governance where religion is given a higher pedestal against national and geopolitics. Nations will continue under the forces of micronization and limited macronization spinning around the political power axis with a bipolar force that ideally may shift by replacement, though not happened so far under political governance system even if the ideology may force people to believe it is religion that is ruling the state. It is only a make-believe refraction. The main reason is that belief in God in any of the three formats (God, Gods, and no-God) is strictly

personal. It cannot come out without political wrapping for governance of a nation whatever a constitution may call it.

35.2.4.2 Axis 2—Belief System

Religion is the most powerful and original belief system in control at the moment, but, unfortunately, not the most benevolent when human species have to live together where birds of different feathers have to flock together but unfortunately cannot that easily. Religion is extremely powerful because God can sway a human into unexpected wavelengths beyond the acceptably designed personality factors and for the same reason into non-benevolent behavioral formats also. History is replete with examples of such behaviors that may put rationalization into shame. Humans, especially individuals in the act, have no control over it. Humans cannot live without God of any kind. The power of religion lies in the perceived security, whereas the power of politics is on apparent security. This is also one of the reasons why religious power will be secondary to political power, though at times one may experience a lead over the other. That is a temporary feeling because they are not on the same track. That is also the reason why they exist as separate axes which could also be said apparent (politics) and perceived (faith and belief system), respectively, though not recommended for this study. The weakness of religion is that its power centers can waver beyond acceptable human concerns. It is a normal behavior under extreme threat perception. It is a game jointly played by the law of invariance and law of limitations. The inability of religious power to realize that there will always be a counter-force (another religion) to balance it gets lap dissolved into the urge to become the only one, the monopolar ideology. This is more for the religious axis than the political power axis. That is another reason why political power axis is more stable and balanced. It is not possible, and even if it happens, it will be short-lived causing a polar split which has happened in every religion in minimal measures only to enlarge later since they originated. They are the divides in religion into various sub-religions. These divides are also examples of religious beliefs even in no-God subsystems. As mentioned earlier, it is this tendency to split in religious beliefs that caused the generation of the power axis wrapped in a better term called politics.

35.2.4.3 Axes Synchronization—Possibility

Smooth running of governments and the governmental systems can be achieved by axes synchronization. All nations barring a few are successful in it. Others balance by either micronization (cookie splitting along the fault lines) or forcefully synchronize the axial separators to balance. It is important to understand that the binary axes operate the entire global human system. The axes do not operate national systems. What the nations experience is the binary axial polarization depending upon their position relative to the global axes. That makes the nations govern their countries with relative ease. That also is the reason why the global system will not align as a

unified system in the global perspective ever. It will be too much of a concentrate to govern. Axes synchronization happens when the disharmony or resonance is minimum. The tuning fork of governance will not hum if kept close or if the axes are not synchronized. This silence will be seen in the noise in governance in terms of unnatural conflicts in governance. Unnatural conflicts are those associated with anarchy like low pressure formation and accumulation in a tropical revolving storm (TRS). This was evident in the case of many countries in the world at one time or another. Disharmony in governance cannot happen if there is axes synchronization. It is possible to synchronize the axes by governance. It has to come from the political binary, not from the religious polarity. It is the role of governments that also includes the people in national security.

35.2.4.4 Centrifugal Governing

Centrifugal governing is an interesting idea where the government puts all the stakeholders in single stake. It is one by getting stakeholders together by a unitary attraction. But the methods of doing it are left to the choice of governments as the governing system will have to strategically identify them. For that, it has to be a part of national security strategy. All the governments are attempting it. There are discords. Discord is part of governance. It is necessary to maintain checks and balances. Negative discords that damage can be minimized as people become aware. Informational security, the ninth element of national security, has a serious role in making the public correctly and rightfully aware of the nature of governance. The vortex in the centrifuge is caused by the axes conundrum. Governing from within the centrifuge is what the axes do. Cold War, ISSL, superimposition of Crimes3+ over rule of law, and governance—all such offsetting detonations by the anteforces within governance originate from the axes imbalance. Centrifugal overnice can smother such situations.

35.2.5 Concept of National Security

After the preliminaries, it is about the national security itself.

To recapitulate briefly, “*national security is about the overall well-being of the people of a nation, as defined in this study, where the nation is the largest human system identified and recognised as a nation governable by a government by the rest of the human systems. Well-being of a people is the sustainable achievement of apparent security aligning with perceived security wherever possible by optimising the elements of national security and integrating the identified terrains by governance. The goal is a variable along the moving target of NS_{max} . In this process, a government ideally can only provide apparent security comprising the needs of the people not the wants as per their perceived security. But the governments should respect the perceived needs and align them in such a way that the perceived security does not clash with apparent security and impact on the factors of*

well-being. The perceived security component in the wholesome national security is the spiritual security."

The term, national security, evolved much later after the formation of nations. The concept of group security was germane to humans. National security is a distinguished form of group security applicable to nation states. But its principles can be applied to any formal group—corporates, other organisation, societies, and families—from the largest to the smallest, with appropriate modifications in governance and administration. That is how the concept has been seen in the definition, though the purpose of this book is to provide a different perception to the concept of national security related to the governance of a nation in a people-centric approach.

It is reiterated that national security is beyond the concept of mere physical security. It is defined in many ways according to prevailing perception.

In this book the concept of national security is defined as "the measurable state of the capability of a nation to overcome the multidimensional threats to the apparent well-being of its people and its survival as a nation state at any given time, by balancing all instruments of state policy through governance, that can be indexed by computation, empirically or otherwise, and is extendable to global security by variables external to it."

The measureable state of national security of a nation at any given time is projected as national security index for comparative and feedback assessment in governance. This requires identifying appropriate metrics.

35.2.6 Elements of National Security

The constituent elements of national security were examined within these precincts. They are visible through the fog of misconception of the erstwhile Cold War and subsequent conflicts in the name of terror and militancy. This study records 16 identified elements that are placed in an informal hierarchical order, though there is no recommendation to study them in that order. The earliest element identified is military security and, the latest in the array of elements, microbiomic security limited to human biome for the present. Each of the 16 elements is still evolving and expanding. They were identified from acceptable parameters by disregarding those that were conditional to the concept in varying forms. The underlying characteristic of the elements is their mutual inclusiveness. There is always a trade-off in governing one that will reflect on others. Therefore, the elements have to be optimized in governance. The elements, therefore, are complementary to each other. These elements are explained in Chap. 6. To recapitulate, the 16 elements with author's aphorisms are as follows:

1. Military security, *the ultimate in human challenge.*
2. Economic security, *the solvency paradigm.*
3. Resource security, *the chain of sustainable persistence.*
4. Border security, *the paradigm of joint ownership.*
5. Demographic security, *the overarching human stasis.*

6. Disaster security, *the shield against catastrophes*.
7. Energy security, *the standard for advancing life*.
8. Geostrategic security, *the context of global neighborhood*.
9. Informational security, *the state of public awareness*.
10. Food security, *the postulation of zero hunger and malnutrition*.
11. Health security, *the emergence of productive human*.
12. Ethnic security, *the accord in equality and equity*.
13. Environmental security, *the act of balancing natural capital*.
14. Cyber security, *the virtual odyssey in human perception*.
15. Genomic security, *the assurance of flawless inheritance*.
16. Biomic security, *the mystery element of symbiotic survival*.

The interplay of the mutually inclusive elements takes place in eight terrains: land, ocean, airspace, and contiguous space as separate geophysical terrains, and deep space, cyber space, genome, and (human) microbiome as non-geophysical terrains (Box 35.1).

It is important to understand that elements should be optimized in governance for maximum yield in national security.

Box 35.1: Editing Mythical Times for Elements and Terrains

Sanskrit, among some others, is considered one of the languages of the mythical times with rich texts and scriptures. Hence, if translated into Sanskrit (a la *panchabhootha* in Chap. 5) the 16 elements and eight terrains will be roughly *ṣoḍaśabhūtha* (shodāśabhoothā) and *aṣṭakṣētra* (ashtākshēthrā).

35.2.7 Terrains of Governance

A terrain is an independent continuum by itself with exclusive characteristics. They are dimensionally different for maneuvering. At the same time, applicable terrains need to be integrated for national security governance. A domain is the focused part of a terrain for maneuvering. Eight terrains, where the game of national security is competitively acted out, are presently identified in this study. They are, in sequence of appearance, the land, ocean, air space, contiguous space, deep space, cyber space, genome, and human microbiome. The terrains need to be integrated by governments, while governing to maximize national security. They need to be visualized as a collective continuum and not individually for governance by national security (Fig. 35.1).

It is important that terrains are maximized and integrated into national security for maximum yield in governance by national security, because of them being exclusive to each other but inclusive to national security.

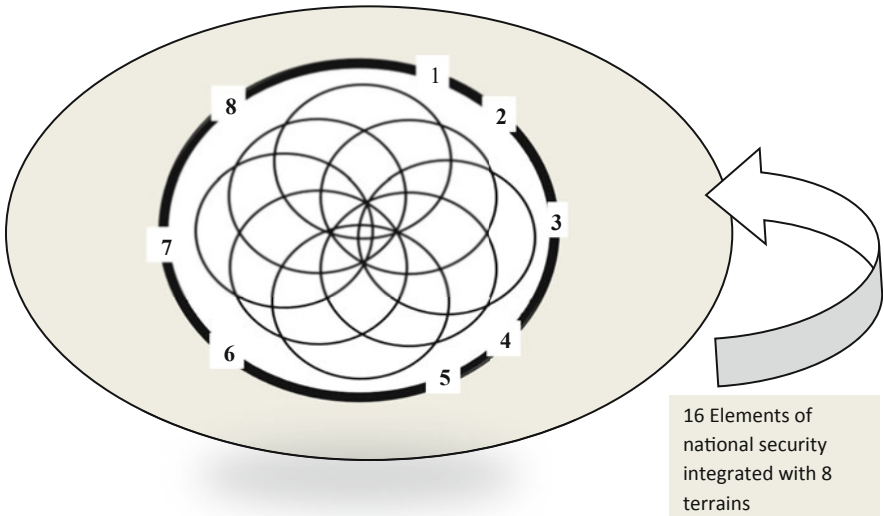

Fig. 35.1 Terrain integration of national security elements

35.2.7.1 Land

Humans will ever remain land-clasped. The land area will increase or decrease periodically to the rise and fall in sea level and internal fresh water inundation within the natural limits. The natural limits are based on the quantum of water on the planet in solid and liquid forms. That is a huge amount. The land also comprises landlocked seas and other water bodies.

35.2.7.2 Ocean

Ocean is the vast expanse of water continuum over land with high salinity and pH value. It is the terrain that has been familiar to humans since primitive times along with airspace. This study finds humans have been associated with the ocean as close and early as they were with land and air space, though they started moving in the ocean much before in air space. Governance should see ocean as part of land or extension of land, but different as a terrain where a human needs a vessel or a stationary platform to sustain.

35.2.7.3 Air Space

Human association since the days of yore was based on their intellectual preoccupation with birds that fly.⁵ “If they can, why can’t us?” became the quest and slowly airspace became the third terrain developed adjacent and over the land when commercial interests fired human ingenuity to invent flying machines. The geoproperty of air space separates nations by the verticals along the land boundaries and ocean area limits.

35.2.7.4 Contiguous Space

The contiguous space is a term used in this study to depict the fourth terrain of national security which is part of the outer space adjacent to the upper limit of air space extending to the limits where regular human activities subject to space laws relative and continuous to Earth take place presently. It is a kind of human work area in outer space as a global common and thereby geophysical. The outer limits are not specifically earmarked, but expected to be in the lines of the law of the sea or otherwise 1 day. Till then, the extent of contiguous space may be taken based on the reach of spacefaring nations, but under the global commons principle since many nations do not have the capabilities to directly exploit it. The national interests of those countries also need to be respected under international law.

35.2.7.5 Deep Space

The deep space as a terrain of national security commences from the outer limits of contiguous space whichever way it is limited in use extending into the interstellar space beyond the solar system and as divided in future under unified space laws relative to Earth. It is not the deep space as defined by the International Telecommunication Union (ITU), starting from a distance of two million kilometers from the Earth’s surface. The measurements of distances in deep space should be done under stellar parallax⁶ based on spherical trigonometry similar to what is done in the ocean. There is a requirement to include the part of deep space within the solar system under a unified law of space applicable to national security governance.

⁵Birds figure more than marine species in the scriptures and mythological depictions of human systems. Early humans wanted to fly like birds.

⁶Stellar parallax is the apparent shift of position of any nearby star against the background of distant objects. This is not something new. The first known stellar parallax measurement is thought to have occurred in 189 B.C., when Hipparchus (190–120 BCE) a Greek astronomer, used observations of a solar eclipse from two different locations to measure the distance to the moon.

35.2.7.6 Cyberspace

Cyberspace is the intricate worldwide information environment in a network of computer and information technology-based information systems including intelligent systems with embedded processors, programmes, and controllers. Cyberspace is virtual and dynamic and is subject to cyber laws as amended by the governments. Cyberspace describes the virtual world of computer systems that extends across a global network of computers.

35.2.7.7 Genome

Genome is the entire genetic material of an organism comprising DNA.

35.2.7.8 Microbiome

Microbiome is about the biota that resides in and on the surface of a living thing symbiotically engaged with the life of the host. This study has considered only the human microbiome for the present to the point of the importance of the biota in national governance related to many of the elements. It is also classified as a separate terrain which may change in future by merging or expansion, but not by redundancy.

The human microbiome is the aggregate of all microbiota that biotically reside on or within human body. The human microbiota symbiotically occupy the skin, tissues, biofluids, skin, mammary glands, placenta, seminal fluid, uterus, ovarian follicles, lung, saliva, oral mucosa, conjunctiva, biliary tract, vagina, and so on. They are microbial cells harbored by an individual human. The role of these symbionts on human life is being studied seriously. This study considers human microbiome a developing terrain that the governments cannot neglect in relation to national security governance.

35.2.8 *Balancing Chaos—Threats, Risks, Uncertainties, and Chance*

Threats, risks, and uncertainties are the factors that will impact governance. They have to be visualized seriously and separately beside examining their interactive behavior in the run for governing for NS_{max} . The difficult part is separating them from each other and understanding them in clear perspective because all of them have similar characteristics in their behavior, especially for the uninitiated. It is important to understand them because each of them has to be handled separately, not identically.

Threats, risk, and uncertainty when mixed with chance will invariably be chaotic, a situation that warns the interventionist that system can go abnormal in results. It is a deadly cocktail in national governance. Governments experience it like a ship in a storm. Chaos happen in dynamic systems where the random states of disorder get into deterministic laws that are sensitive to desirable state of affairs. That is the reason why anarchy, if not attended to immediately, leads to impending doom that may micronize or totally collapse a nation (Box 35.2).

Box 35.2: Chaos and Break Up (Micronization) of Nations

The down-to-earth term used to explain decline and death of a nation is disintegration or breaking up in the geostrategic lexicon. This study recommends micronization. It is a bit more respectable considering nations as dignified human systems. Every human and therefore every group is a dignified entity whether force (or proforce) or anteforce relative to the prevailing social order. Chaos can break up a nation. There are experts and scholars who believe the Westphalian order and control systems of nation-states, and more emphatically of the cooperative derivative of nation-states, the supranation,⁷ can breakdown if violence and violations inhumane the order and balance piercing the human system boundary. This study doesn't find it a serious matter in the advancing sapien world where the order will be progressively intelligent. Chaos, including externally created to break up a nation, therefore, will be governed and contained. It also means the risks and uncertainty will be handled and chance harvested. Chance harvesting is term used here meaning negative chances are weeded out and positive chances are cultivated. It is a game plan for governance and needs further research.

The important point here is that the anarchic form of direct governance need not break up or micronize a nation if governed to contain chaos. There are examples.

35.2.8.1 Threats

Security is against threats to human survival aptly perceived, but not inflated. The TMC (threat matrix cube), identified in this book, is recommended for appreciation of threat analysis. It is vital for security assessment and strategic planning. The "cube" does not take into consideration the wild cards: unforeseen events in the world that could cause a major discontinuity or fundamental change in the security objective. The wild cards are external to it. Any identified threat can be sited within one of the cube characteristics (type) unless accompanied by a wild card.

⁷ A supranation is a collective cooperative of nations that join together as a nation beyond the Westphalian boundaries of sovereignty as a system with a defined boundary. It is an interesting concept at least to perceive and conceptualize the world becoming a supranation for global security, fictional for the moment.

35.2.8.2 Risks

Risk is the prospectiveness of missing or delaying the end objective, the goal in an activity. Governance may face turbulence and sway with respect to goal under risk. There can be loss. There is an unsuspecting or astute exposure to danger under risk. Therefore, governance needs to anticipate risks at any time and hedge them against damage. Risk points out negative consequences in governance intervention. Risk can be assessed by premising forecasts for future analytically or cuing on intuitive assessments of situations from past experiences.

35.2.8.3 Uncertainty

Uncertainty causes consequences in governance which could also result in positive outcome. It is also associated with situations. Uncertainty is when things happen against the appreciation and premises. Uncertainty cannot be foreseen or predicted mostly. It could be mistaken for risks or chance and vice versa. Uncertainty is covered by the fog and friction of an activity situation.

35.2.8.4 Chance

Chance plays a major role in changing the world. Incidence governed by chance like the 11 September 2001 terror attack in the US or the 26 December 2004 tsunami disasters in Asia are examples. Every chance has a cause since a chance event is an effect. The effect becomes chancy when the cause is not known. The next question is, can one create a “chance” event for an accident if in the overall benefit of the world it is better? For example, assume that a government welcomes an intelligence report about a terror attack and allows it to take place with an eye on opportunity to achieve a choice objective—say...? Well, that is a dangerous question this book dares not ask!

35.3 Rule of Law

The primary task in national security governance is making and enforcing law in the process of establishing the rule of law. Rule of law applies to every element of national security in every terrain. The specificity of law for rule of law will depend upon the peculiarities of governance with respect to a human system. That is the reason domestic law varies from country to country. At the same time, international law has to have a universal character in global perspective. National security has to be established under rule of law where the government establishes domestic laws peculiar to the human system characteristics of the country, but at the same time

without violation of international laws in modern times. This study recommends enforcement friendly laws for establishing rule of law. Enforcement friendly means laws that are easily applicable without prejudice to the human justice system executed speedily. There are five factors in enforcement friendly law. These factors provide clarity in the unlawful activities that the nation may face, the jurisdictional aspects without ambiguity, enforceability in the concerned human system, expediency, and abuse resistance. The much used term “justice delayed is justice denied” is not applicable to the expediency factor of enforcement friendly laws. Expediency is related to cost and time of governance. Delayed enforcements can increase cost and delay the speed of governance which is not desirable in competitive governance.

35.4 Prospecting National Security

Prospecting in the context of this study means seeking by careful examination. Prospecting national security includes identifying and studying the indicators of human well-being carefully. In this process, it is important not to mistake non-indicators for indicators. This knowledge comes gradually. For example, a much-hyped parameter to indicate a nation's health is suicide rates. Suicide is a matter of mental process among those who commit the act. A process in which, generally, the prospective victim shifts rational thinking notches below the normal. Just like a physical inability cannot be taken in isolation as a direct measure of a nation's well-being, decline in mental ability momentarily in an otherwise emotionally normal person too needs appropriate consideration in maximizing health security. Suicide certainly is a mental letdown under specific circumstances for an individual. It has a genetical format. Psychologically, it could turn into a game for a reward often unknown to the victim. Some such acts are simply crimes (insurance fraud). Such indicators are not directly valid for assessing NSI. Questioning a parameter, recommended as an indicator, in this manner at every stage of its identification is necessary before acceptance. There are many such parameters that may misguide prospecting national security.

An interesting aspect is that seldom history has witnessed a reversal in the aftermath of an incident whether it is war, terrorist attack, economic depression, disaster, epidemic, or any of those that affects national security. Everything repeats. In some cases, detailed studies will be carried out. Every investigation will end up with contrasting views, each laced with an aura of selective mystery. The reactions to the incident will slowly dissolve into day-to-day life and then set aside. The incident will repeat as another wake up call, only to continue the cycle.

Stephan Flynn's, *America the Vulnerable: How Our Government is Failing to Protect Us from Terrorism* (Chap. 33), stated that despite all the pronouncement post the 11 September 2001 terrorist attack in the country, the government was not in a position to protect the people of the United States. It is equally applicable elsewhere where countries have fought wars one after another or faced terrorist attacks without learning lessons. Disasters take place at cyclic periods and one can even predict

when the next one is going to come. The amnesic approach of the humans to future with absolutely callous or totally blind attitude to history and the past is forlorn and, at the same time, amazingly close to the behavior of animals toward their past. They forget an incident in seconds and depend more on their instinct to survive the next moment. Does this make the human brain, despite being at the head of the long tunnel of evolution, still animally primitive? Why humans shift to the animal format in a tunnel syndrome⁸ of evolution is understandable if one can visualize the tunnel behavior; forward moving in darkness in the quest for survival in the company of all in the life farm. It's not the legendary arc of Noah in the Old Testament, but the tunnel the author would like for better understanding of the inseparable dissolution of life forms with each other. The life forms have no other choice, but to move forward in evolving in the darkness of the tunnel without even thinking of the light at the end. The tunnel is endless relative to an individual life form.

In this paradox, humans may struggle through informed governance and find a path through it for development. The process is too slow for generations to get to now even themselves. Adjusting with the pace of this process is very important for the humans to avoid slippage, like in a belt that links two different wheels in a drive. National security governance may have to induce the friction that is necessary to synchronize the process with the pace at which the evolution progresses.

35.5 Prospecting National Governance

National governance in this context is of the people and by the people in a nation. This is universally acceptable. It is also acceptable that a nation needs to be governed for its dynamic move forward. It is from this lemma a nation can also be defined. One such definition is that a nation is a largest human system entity that is governable as a geopolitical entity.

Humans govern at the macro level in two different ways which have been reiterated to drive home the two metaconcepts of governing for ease of explanation and conception: indirectly, through a government that acts as an agent of the people under acceptance or nonacceptance but submitted to, and directly, without an agent by the people themselves that may not last long and can often end up in chaotic imbalance which in turn may lead to micronization or total constructive ending with the loss of the nation. People participates in both in one way or another, hence people's participation is not a factor of governance. There cannot be any governance without people's participation either by acceptance or nonacceptance. Consent and conflict are natural to peoples' participation for governance. The metaconceptual appreciation clears dissonance of any sort that may affect decision making. Confusion in explaining governance often comes out of dissonance created by definitions.

⁸Contrary to the much used chain syndrome. This study considers evolution being continuous is not similar to a linked chain but a protruding tunnel being continuous and surging.

One such misappreciation is the overuse of the term democracy and the projection of it as a separate system of governance that is most modern, advanced, and the best. It is not. This study discards this statement in toto, because (1) the same term is used to explain the form of governance more than 2500 year old in Athens, (2) there is no form of governance without “total” human participation anywhere in the world so far in the history of human system. Therefore, this study calls the governance through an agent democratic and without the agent anarchy. Under no circumstances, anarchy should be termed as confused or turbulent form of governance. There are examples that states under anarchic governance had shifted to more balanced democratic governance without loss of state by admitting agents to govern for the people through various forms of admittance including electoral, monarchic, military, and dynastic formats.

The bottom-line of all types of governments, whether democratic (as explained in this study) or anarchic, is governing humans by humans within the system. The question, which form and type of governance are better, is strictly relative to the time and people. For universal comparison with respect to a time or period, it is necessary to have an index for which the NSI without the application of any country-specific factor is seemingly the best according to this study.

The role of a government is to protect the nation first and then the people. It is similar to the role of the captain of a ship at sea. The safety of the ship comes first and then safety of the people on board. In the case of a nation, how the government will perform its role is the prerogative of those in authority. This role will not change, but the prerogatives will continuously change based on the changes in the nation system environment. The target or the goal and its character will not change under the national security concept. It will be human well-being as defined periodically. The approach path of governance will be to deliver and become more and more productive.

The future of governance will not change vastly, but for the changes and moving toward to the situation and environment beside the demand from people. But once the focus is on the fixed goal, human well-being under national security, the destination is clear for all. So, the change will be in the approach which will be on the role, procedures, and strategic applications of governance.

The critical factor in governance is not the form, type, or any other characteristics. It is the destination. There is only one destination—human well-being under national security. Every nation will be able to govern for maximizing the NSI provided the destination is known and clear. Ultimately, national security governance, in a nutshell, is about optimizing the identified elements and maximizing the terrain properties wholesomely by integration for maximum human well-being. That is NS_{max} . That will make the humans to inch toward sapient humans.

Glossary¹

Abstraction An abstraction is an intellectual perception that is neither real nor unreal, but purposefully existent as a support to existential behavior as a faculty of human intellect. Abstraction is indefinable unlike real and unreal, but intellectually perceptible and thereby applicable in the process of life including governance. Abstraction allows human intellect to simplify the complexities of intelligent life by extracting essential and critical objectives from complex parameters that govern existential life.

Adhyasa *Adhyasa* occurs in governance when there is misconception on the part of the government and people and the stakeholders including those in governance. *Adhyasa* is a vedantic term highlighted in *Brahmasutra*, meaning false superimposition of one characteristic on another. An example is superimposing a rope onto a snake. *Adhyasa* literally means “superimposition” in the sense of mistaken ascription or imputation to something of an essential nature or attribute not belonging to it. It is an apparent presentation of the attributes of one thing in another thing. This can happen in any decision making situation.

Adversarial Misconception An adversary is a competitor in live situation. Inability to recognize, understand, or appreciate the adversary can cause adversarial misconception that in turn can weaken the strategic and tactical decisions in a competitive environment.

Air Space Maxima Air space maxima is a term used to describe maximization of air space property including air space advantage for national security maximization by governance.

Anarchy Anarchy is one of the two forms of governance where people govern themselves directly and not through a government. Anarchy may lead to chaos in a human system if not timely arrested.

Anteforce Anteforce are those individuals and groups who oppose the centrally accepted governance of a governmental system, by remaining internal to the

¹Note: The glossary is based on this study and is applicable to it. They are subject to change.

human system that is governed, with or without external support. Anteforce has the power that could be utilized for governance by national security if turned around. The opposition as defined in an electoral government is not an anteforce, but part of government for maintaining checks and balances by supporting positive governance.

Anxiety Models Anxiety models are the human belief system perspectives that cause or induce anxiety.

Apparent Security Apparent security (need based) is what governance by national security can provide by satisfying the needs of the people. A government can provide apparent security, but the wants of the people otherwise called perceived security (want based) cannot be satisfied directly.

Aspect The aspect is a term used in handling threat. It is the relative positioning of threat and target. It is how a threat is perceived from the target (primarily) or the target is perceived from the threat (secondarily) for decision making in handling the threat. The aspect of threat to target and its variations are important in factoring decisions in governance.

Astrodynamics Astrodynamics is a term coined by the author for the hybrid study of phenology and astrological or associated mathematical calculations to appreciate the time functional analyses of periodic events in biological life cycles related to human intelligence outputs under the influence of existential factors. Human life is in organic format and therefore susceptible to cyclic variations along the span of existence. It is also dynamic. The term is thought up under the principle of falsifiability for further research.

Belief System Belief system is about what people believe realistically, unrealistically, and abstractionally. Belief system includes sets of principles, tenets, and follow-on formats of life that together become the basis of existential life in various processes and governed codes of conduct. Belief systems in an individual or group originate from the mental process cued and stimulated by the survival pangs, especially the inherent insecurity, as the driver. Belief systems drive the activities of humans in a system or personal life.

Binding Energy Binding energy is the consensual energy available for activities in a group which is the binding force between the members of the group based on the degree of cohesion existing between the members. The binding energy of a human system will be according to the targeted objectives of the activity and belief systems.

Biomic Baby Biomic baby is the author's term for a child born under the natural process of delivery (vaginal delivery) where the child carries the maximum biomic signature of the mother.

Biomicros Biomicros are another word used for explaining the microbes of a microbiome.

Biomodel Biomodel in the present context is a standard model which can be used for decision making in a live human system. In this modeling, a live relatively micro-human system is analyzed in relation to a particular intervention and

subsequent behavior which can be amplified to forecast changes in a similar but macro system for governance.

Caveat Caveat is a provisionary caution that the statement is subject to the situation, condition, stipulation, and limitation of study and as felt to the best of available knowledge.

Chance Chance is the possibility of something happening that skips the conscious mind and hence happens as if suddenly.

Chance Farming Chance farming is author's term for creating a situation inviting chance, still a chance, expecting a positive turn out or yield. Actions carried out under optimism, positive feelings, expectations, and so on could turn out to be chance farming. Planning process provides a host of opportunities for chance farming.

Chaos Chaos is disorder in a system. Handling chaos is the process of turning disorder to order or preventing or preempting disorder.

Civilization Civilization is a term used in the present context to describe human system as an intelligent collective. The term is different from the assumption of affluent and developed people. In this context, civilized means the ability to use the intellect for collective survival in responsibly humane or sapien manner. Humans are considered relatively civilized within the absolute global system as a unitary civilization.

Coastland Coastland is a geo entity other than an island that has direct access to ocean. A geo entity for terrain-specific studies in national security can be a landlocked nation, coastland, or island. Each needs to be treated separately in strategic national security.

Cold War Cold War is a terminology attributed to the implied hostilities under political tensions between the erstwhile Soviet Union and the United States that lasted directly and through the allies known as the Eastern Block and Western Block, respectively, following the end of World War II. The geopolitical tensions that began in 1947 continued till 1991 till the dissolution of the Soviet Union. It was a period that the author calls Third World War which virtually challenged the wisdom and upwelled primitiveness of human systems under the bipolarity of power axis in spite of the apocalyptical sufferings the world population experienced in the two world wars preceding it. Interestingly, the world advanced on fast track in science and technology during this period, affirming that the adage of psychology of invention could be destruction but benefitted by transfer of science and technology for human positive advancement in various spheres. The world seemingly became wiser and responsible in geopolitical thinking post-Cold War.

Commons Commons are global properties that the humans can benefit from jointly. Commons for this study are those resources, in whatever form they are, available for the common survival use of humans. Among them, global commons are what are claimed by the global population and national commons are those claimed by the people of a geopolitical entity other than the global commons. Commons are not owned privately, but collectively either globally or nationally.

Conflict Minerals Conflict minerals are part of conflict resources. These resources are precious or strategic under high demand and often invite belligerent accessibility that induces prolonged conflicts. There are identified conflict minerals which are brought under law and regulations internationally as well as domestically. Conflict minerals cause armed conflicts and human rights abuses to natives.

Conflict Resources Conflict resources are natural resources extracted in a conflict zone and sold to perpetuate the conflict and fighting. More than that, any natural resource such as land, water, etc. can be termed as conflict resource if that is a cause for disagreements, disputes over access, control, and use.

Continuum Countries Every country is a continuum country unless it is on a transition between the end of one continuum and before the beginning of another on a fresh start. Understanding the exactness of the continuum of a country is important in premising for planning national security strategy. The continuum transition is the period of interruption in the life of a country. This means the length of the continuum so far, the probable span into the future, the exact position of the country in the continuum span at a moment in time, and the direction it is moving. Within the continuum span, every country, being a human system, will ideally have its birth, growth, decline, and death. The longest surviving human continuum will possess the strongest cultural dynamics. Though not necessary, anarchic governance may lead to new continuum and, certainly, when followed by chaos.

Coup d'œil Coup d'œil, as intended by Clausewitz (On War), is the ability of the commander to premise and forecast incident intuitively in a military and war scenario. It also means taking an all-around comprehensive view in a decision situation. Literally, it means "stroke of the eye" in French

Crimes3 Crimes3 is the author's term to three transnational crimes of trafficking in which various stakeholders are involved unknown to each other including authorities who govern. These are global cross-border crimes that support many power positions in governance. They are arms trafficking, drug trafficking, and human trafficking. The crimes could remain perpetual as they support the needs of many.

Crimes3+ Crimes three plus means addition of another crime in traffic to the already existing crimes 3. The transnational crime of organ trafficking is already holding a place in Crimes 3+.

Cyber Governance Cyber governance is governing the cyber security element of national security by national governance by integration of all other elements and terrains of national security.

Cyberspace Maxima Cyberspace maxima is a term that describes maximizing the cyberspace property including the cyberspace advantage for national security maximization by governance.

Cybernetics Cybernetics is about causality in a continuum. In this case, it is taken as the effect turning into a cause. It originated as a study where the outcomes of actions are taken as inputs for a process in generating outputs. Cybernetics is an old subject on governance. Plato used the theory to explain governance and government. It was modified in the nineteenth and twentieth centuries. Feedback

systems appear in the cybernetic mode, especially in the study of automatic control systems in humans and their creations.

Cyber Security Vs. Cyber Security The former is an element of national security and the latter is about information security in cyber space. Cyber security, the element, includes cyber security, the protection factor. It is for the government to intervene, whereas the latter is for experts in information security to act upon. This difference is important.

Decision Accelerators Decision accelerators are information and other cues that help to make a decision fastidious, often crossing the limit defined by critical time which is when a decision is most appropriate. Most of the policies and plans cross critical time because of the absence of decision accelerators, not exactly inertia in a human system.

Decision Decelerators Decision decelerators are those that impede or induce friction in decision making process. It is not absence of decision accelerators.

Demographic Buoyancy Demographic buoyancy is the stasis of a human system that keeps it positively productive toward national security governance.

Demographic Density Demographic density is outwardly similar to population density. It is a term used in demographic security optimization in national security governance. Though it is not strictly population density which is population per area of land, demographic density is the quantum pressure that a nation and its government feel under pressure of population. There can be governments for whom demographic density is more than the population density or vice versa. Governments under maximum governance may be able to keep demographic density feeling less than the population density arithmetic.

Demoslip Demoslip is the term suggested for human population impact explanation in national security governance. Demoslip is when the demographic density doesn't match with the actual feel of it in decision makers. Some may feel it is low and not sufficient; for some it may be in excess. Demoslip can impact a governance. Both ways, it can be a cause of stress in the respective life system.

Differentiability (Human) Differentially as applicable to humans in national security governance is that every human is different from another. It is not opposite to singularity, but apposite to it in governance. Differentiability can be appreciated only in the presence of singularity in human governance. The differentiability is exclusive to the intelligent humans.

Dysbiosis Dysbiosis is microbiomic imbalance in a system that causes adverse effects. Dysbiosis is under serious study in human health issues caused by microbiomic imbalance. Dysbiosis can happen on or inside the human body.

Economic Warfare Economic warfare, also called economic war, is an old fashioned governing technique applied in geostrategic context by one nation, normally an economically powerful one, over a lesser another with the objective of economically weakening it. This method has acquired different transformations in course of time and is still continuing. This study cautions that economic war can be globally destructive from the point of view of economic security of all nations including those engaged in it. A biomodel can be the impact of Covid

19 worldwide to study this caution seriously and its economically destructive outcomes. It cannot be denied that there are certain positive sides to it when other methods fail.

Element of National Security An element of national security is one of the constituent parts of the concept. It is an inclusive constituent that needs to be optimized by balancing trade-offs in application. Some of these components may merge or become redundant in future. There are also chances of new elements coming up, as national security concept evolves.

Event Horizon of Aggression Event horizon is a physical term meaning the edge from where there is no coming back. Though not absolutely similar in national security studies, it can be compared with the edge of the entry point of a black hole, the fall edge of a waterfall, or the parapet less edge of Leoni's well mentioned in this book. Event horizon of aggression, therefore, is the point beyond which aggression will happen and cannot be stopped.

Evolutionary Frequency Evolutionary frequency is the natural rhythm at which evolution advances as if in an inkblot. It is the cadence of continuous movement forward in evolution. It cannot be increased or decreased artificially. The doubt here is about the surge in which there are chances of evolution moving backward. It is called devolution (see surging).

Failed State A state cannot fail. Only governments can fail. All the modifiers such as failed, rogue, flawed, and so on are associated with failed governments, not state.

False Positive False positive is an expression for something that semantically means existent and real, but strictly shouldn't have been there. Governance cannot get away with it, but can focus on eliminating a false positive since it doesn't serve any purpose. There are no false negatives.

Falsifiability Falsifiability is the competency of a proposition, statement, theory, hypothesis, or accepted idea that holds a possibility of being proven wrong. Falsifiability is essentially of adopted method and testing. Falsifiability of a theory confirms its testability. Though initially originated for demarcating science from nonscience, this study considers falsifiability applicable to knowledge in general.

Flybox Analysis Flybox analysis is a method to locate the threat relative to target like a fly approaching a target in a nonlinear dimension and varying intensity based on proximity that will keep changing back and forth relative to time. The threat to a target in governance can be tracked in this manner for decision making.

Force Negative Force negative is a threat that is unreal, but felt and assessed under anxiety and confusion in governance similar to fog and friction in forward planning. Force negative can be quite or equally costly like force positive in governance.

Force Positive Force positive is a threat that is real and identified correctly in the threat matrix cube and appreciated in the fly box. The threat, its aspects and its situational nature, explains the force positive, the expression of an actual threat that exists unlike a threat perceived under anxiety. Force positive is real and force

negative is unreal. Governance should be devoid of force negatives in the decision model. Decisions under force negatives will lead to wrong directions. Force positive is an expression of a threat that may damage the target positively. It is real.

Forward Ethnicity Forward ethnicity is a recommended mindset that sapien humans may adopt in their interaction with fellow humans in the present. This is under the assumption that interpersonal relations will improve as evolution advances. Humans advancing within the worm tunnel of unitary civilization may evolve more and more positively. If that is so, human interactive behavior tomorrow should be better than today. It is visible more so in ethnic behavior of the present generation of humans compared to their ancestors. This kind of behavior advancement can be created in the human system by optimizing ethnic security governance without waiting for the future. The present day individuals can look at each other in the advanced manner as their future generations will deal with their counterparts then. This will give a time jump for humans in their well-being. This is forward ethnicity which is opposite to reverse ethnicity. The collateral to such behavior could also be positive advancement of the next generation, a step ahead of what they would have otherwise achieved by naturally rhythmic advancement. This statement is hypothetical.

Governance Governance is a human collective and cooperative activity by which they, being a socially interactive species, retain their social affiliations and affirmations that are essential for existential survival. The highly intelligent cooperative hive mind makes it possible for humans to live together in a social system by governance, either through an agent or direct, by existential default.

Genome A genome is the complete set of genetic instructions of a living thing or form. The genome contains all the information needed to create that organism including the programmes that allow it to grow, develop, and complete its life. The information and the programmes are in the genetic material of the life form which is called the genome. The study of the genome is called genomics.

Genomic Maxima Genomic maxima is a term that describes maximization of genomic property including genomic advantage for national security maximization by governance.

Geno-Biomic Appreciation Geno-biomic appreciation is about the genomic and biomic design format of a human in hybridity. The appreciation does not show any specific difference to say one human is inferior or superior to another. Even the difference between other species with human life form is minimal, but for the intellectual prowess and conditioning. This means the idea of insistence on ethnic differences is a fallacy.

Geopolitical Entity A geopolitical entity is an independent and exclusive human system that is governable under the national security concept. This study identifies 263 geopolitical entities (2020).

Gita Paradox Governance advocates balanced authority, responsibility, and accountability in performing a task or activity. In the three paradigms of governing human systems, there is a presumption that the authorities to whom

the duty is assigned and authority is delegated are expected to feel consciously responsible and are accountable by virtue of authority they hold. There is also presumption that the authorities are sufficiently knowledgeable and informed to plan and execute the assigned duties. In other words, the script is expected to be clear to the actor before action. This is a paradox in absurdity that is highlighted in *Bhagavad Gita*, but has never been interpreted as such so far according to the author.

In the last verse, BG.18:78, it is stated that *where there is Krishna (the Lord) and Arjuna (the supreme archer) together, there will be absolute and balanced results in governance leading to human well-being*. Replacing Krishna with “knowledge” and Arjuna with “delegated” authority can lead to duality conclusions by interpretation. One of them when pronounced will be “those in authority (of any kind) for performing the desired activity or task should possess the knowledge required for that activity.” The second one could affirm the paradox further that “those who have the authority may lack the necessary knowledge required for its execution.” It is author’s interpretation. Authority in governance when not balanced with astute knowledge will result in failed governance.

Global Security Governance and Intervention Global security, governance and intervention (GSGI) is an acronym in this study to explain matters related to the concept of global security which is yet to be established. This term is applied to global security maximization as the world, irrespective of its fragmented format in geopolitical entities, can be governed universally for the well-being of all beyond the present trend of collective (mainly physical) security by applying the principles of national security. In case the UN or its future transcended form of a collective global governance organisation desires to do so, it may need to look at GSGI. Global security as a concept is not within a definable system. It may hold many surprises when the day comes. Until definable, it has to be seen differentially from national security.

Good Order and Discipline Good order and discipline is a term used to emphasize the importance of order and discipline in the organisational concept, especially that of the military. It is also quoted as commented by Niccolò Machiavelli who said to have stated that good order and discipline in any army were to be depended upon more than courage alone. In the organisational context, it is about the manner of conduct of the organisation as an individual entity and also those who belong to the organisation without causing blemish to the organisational good order and discipline. It is basically about human conduct vis-a-vis an entity or a system he or she belongs to.

Governance Deficit Governance deficit occurs when authority, responsibility, and accountability are not balanced and the system governance suffers from the *Gita* paradox.

Government The term “government” in this study means the formal entity established and authorized by the people, through involvement and participation by acceptance or nonacceptance, as an agent of the people under considered authority to govern them within a recognized and governable human system.

Half-Life Half-life is a term used to explain the reduction of certain identified things or processes to half the initial quantum or value in terms of time. Originally used in atomic physics, half-life is the time required for an element to radioactively decay into half the quantity. In pharmacology, the half-life of a drug is the time it takes for the amount of it in the body to be reduced by half. The term can be used in social sciences and other human activities including personal finance to make living decisions based on income and expenditure to better advantage.

Homeland People normally view their land in a higher pedestal than themselves as it gives them the identity of a citizen. It is a normal practice to identify the land with mother or father. In certain cases as in the United States of America, the term shifts to homeland which presumably originated from the migrant mindset of considering the new land as their home. Though terms of convenience are formally used to explain the attachment to one's country with a sense of belonging, the three terms indicate the inherent feeling among humans that their nations are more important than themselves. It reflects in governance by national security too.

Human Capital Human capital has different meanings. It can be explained in terms of attributes that are useful in assessing their economic values. In human investment management (HIM) (Paleri, 2018), human capital is the productive investment value of a human in an activity. It doesn't consider humans as resources, but those who use resources in an activity. Interestingly, the value of human capital can be increased from within with time.

Human Resources (R5) Humans are not resources (Paleri, 2018). Accordingly, human resources can be taken as resources that humans use. The ultimate human resources as identified in this study are air, water, food, shelter, and stored up energy (R5).

Human Sense Human sense is the intellectual sense a human is expected to possess through sentience and reasoning for survival without slipping back into lapsed evolution and having to adopt inferior survival modes by switching intellect in reverse. Human sense is not common sense. Common sense is part of human sense.

Human Whisperer Human whisperers are expected to possess the knowledge for human behavior modification. They are different from animal whisperers. The Human Whisperer can be a human, human system, or organisational entity that will be able to change the behavior of the members and groups including stakeholders and other engaged groups of the system by empathizing, understanding, listening, analyzing, connecting, inspiring, influencing, and engaging through various other innovative methods, for the better. Government has a vicarious liability as well as direct responsibility to act as a human whisperer of the people.

Idealistic Realism Idealistic realism is a concept, posit, or goal that originates from idealistic thinking and gradually transforms into realistic stasis under the induced or acquired natural frequency.

Inkblot Model The inkblot model (Paleri, 2017) is not to be misconstrued with the psychological inkblot tests. It is not a test by itself. It is an identified model that could be used to explain a concept such as an evolution after hypothesis testing by a spread-out extension in a time-spatial system environment, where the variation is not uniform. It can be used as an evolutionary spread in a human system. It can also be applied to plot the spread of various governance parameters of national security (pandemic, sea level rise, insurgency, political power, conflict scenario, etc.) in short spans of time. The term for creating an inkblot model is inkblotting.

Law of Invariance The law of invariance is defined as, *the changes in the core behavior of a human system, while a reality, is too negligible to notice and, therefore, for a psychosomatic system application relative to humans, it is sufficient to presume the model applicable today would be constant in time whether it is past or future.* There is scope for further research in this topic. Under the law of invariance, what an individual human or human system experiences will be more or less similar to what others before experienced. Only the props will be different. The law therefore has to be obvious for the future too. Law of invariance does not apply to incidents and alterations.

Law of Limitations The law of limitations goes in tandem with the law of invariance. It is *“the law of nature that prohibits move by living things to overtake the process of evolutionary frequency by intellectual or other superior moves except where such moves are made within the natural rhythm of process subject to the law of invariance.”* Law of limitations does not limit an activity if it is within the law of invariance. This law too provides further scope for research. Law of limitations should not be mistaken for the limitations of law in the legal parlance.

Limitations of Law Limitations of law in legal parlance are the restrictions imposed by a law for its application. The limitations of law restrict abuse of power according to individual whims and fancies. Limitations of law uphold the principles of the rule of law.

Macro Ethnicity Macro ethnicity is the highest and collective form of all ethnic behaviors that a government has to deal with while governing a nation. Macro Ethnicity is the challenge to governments in optimally governing ethnic security. Macro ethnic differences will exist in any large human system.

Macronization Macronization is the process of enlarging the size of a nation by addition of extra geophysical terrain dimensions.

Metagenome Metagenome is DNA from a group of species collected from environmental samples and sequenced. The study is known as metagenomics. This includes differentiation of genomes in a symbiotic relationship such as human microbiome.

Method Inertia Method inertia is the resistance caused to forward momentum of an individual or a social human system including a nation by the methods practiced in the system, where method is a practice or any such activity initiated for a purpose, but continues even after the purpose is achieved. Method inertia

exists in most of the formal human systems: families, educational institutions, religious organisations, business corporations, nations. . .

Microbiome Microbiome is the aggregate of all microbiota (the microbial community) that reside symbiotically on or within a living thing and elsewhere and comprises their genetic material. They include all the bacteria, fungi, protozoa, and viruses. The weight of the living form includes the weight of the microbiome it hosts.

Microbiomic Maxima Microbiomic maxima is a term that describes maximizing the microbiomic property including the microbiomic advantage for national security maximization by governance.

Micronization Micronization is the process of a nation becoming more than one geontology. Micronization makes a nation smaller in size.

Money Money is not wealth. It is a medium of exchange or an exchangeable commodity that is legally established as the exchangeable equivalent to all other commodities. Money that way is a legal tender for goods and services and a recognized and convenient economic unit for transactional purposes in a human system.

Monocentric Monocentric means one among all nations having control over the rest under power. This state of balance of power is not permanently possible according to this study. Power has to be balanced in a human system. This creates a bipolar situation. In this statement, the assumption is that the world order will be bipolar and never unipolar, except in short bursts of time when changing. It is a kind of critical interval for the human system. Otherwise, the system will crash. It is a natural process. Turbulence in social system shifts the power center more so without warning.

Mountebanking Mountebanking in modern terms is more an economic term about defrauding people of their money directly or indirectly in a way that they do not easily come to realize. Mountebankers siphon public money for their private gains. Public corporations and private operators are involved in it. It is the basic crux of many business houses where the access is only for a selected few at the top. By the time the sleaze flows out, the government will find it difficult to salvage the situation. Even state-owned companies might invest money in doubtful instruments under sleaze.

Mutually Assured Destruction Mutually assured destruction, known specifically by its acronym MAD, has been in vogue during the Cold War period and thereafter, pointing out what a nuclear war can do to the developing world. This term can be conveniently kept aside in today's scenario as the possibility of such a war is extremely rare in the advancing world unless there is absolute irrational deadender behavior on the part of a country or its covert players holding nuclear weapons.

Nation Nation in this study is the largest human system recognized and accepted as a legally governable geopolitical entity. A nation is a human collective as a geopolitical entity with geoprerty rights which is governed or governable responsibly. This conclusion is basically to avoid anomalies that could be

found between geopolitical entities when compared according to their political characteristics. By doing so, the national security principles can be unified for every geopolitical entity.

National Security National security is defined as the “*the measurable state of the capability of a nation to overcome the multidimensional threats to the apparent well-being of its people and its survival as a nation state at any given time, by balancing all instruments of state policy through governance, that can be indexed by computation, empirically or otherwise, and is extendable to global security by variables external to it.*” National security maximization is the considered end objective, the goal, of national governance—governing by national security.

National Security Index National security index is the proposed indexation of national security as defined. This requires globally acceptable metrics. A nation too can identify such metrics and use the NSI, as deems fit, for auditing governance and also assessing itself relatively, though one sided, with another country.

National Security Strategy National security strategy is the strategic governmental interventions crafted by the government, based on the ideated strategic national security, for maximizing human well-being.

Nonmilitary Security Nonmilitary security was a term used earlier along the line of evolution of the concept of national security which was initially conceptualized as the physical security of a nation using military power. It meant national security also depended on other developments such as economic security, energy security, etc.—termed nonmilitary security. But this study deviates from this concept with the finding that national security cannot be differentiated as military or nonmilitary, but as a unitary concept leading to total human well-being by inclusive and integrated governance of all the 16 elements in eight terrain dimensions in which military security is the earliest element that is not exclusive to others. The term nonmilitary security therefore is considered redundant in this study.

Non-state Actors The term non-state actors points out to people who influence national governance from a nongovernmental pedestal of authority. This term is not recognized by the author as such actors are identifiable as anonymous stakeholders who function with the direct or indirect support of one or more states including their own at the top end. The term non-state actor can cause semantic dissonance in decision making.

Ocean Maxima Ocean maxima is a term for maximization of the ocean terrain. In the case of the ocean, it means maximization of the ocean property for national security maximization by governance. The identified ocean property (Paleri, 2002) comprises ocean advantage, ocean resources, ocean environment, and oceanic islands.

Ockham’s Razor Ockham’s razor is an ideated law of parsimony that can be applied to problem-solving, which states choosing the simplest explanation is usually could be the right way of doing it. The principle emphasizes not to add entities without reason while problem solving because it will make a simple issue

complex. The principle is attributed to the fourteenth century British theologian William of Ockham.

Particularly Sensitive Sea Area A Particularly Sensitive Sea Area (PSSA) is an area that needs special protection because of its significance for recognized ecological or socioeconomic or scientific reasons and which may be vulnerable to damage by international maritime activities. The nodal international agency for action is the International Maritime Organization. There can be special sea areas (SA) within particularly sensitive sea areas and vice versa.

People Interrupted People interrupted are those citizens who get caught between conflicting parties in disputed areas, border areas, war zones, etc. Their lives come to a standstill in an arrested manner. There are thousands of such people in disrupted zones all over the world. It is also not necessary for conflict and violence to be a cause for interruption. Epidemics, pandemics, disasters, etc. can interrupt people. People interrupted seriously matters in border security governance.

Perceived Security Perceived security is more about the psychological needs that people nurture for fulfillment. It is a task for governments, though the functions and possibilities are limited. It can be integrated with apparent security by smart governance. Absence of perceived security makes people to act on their own. It is also a need based on wants that cannot be easily satisfied even by individuals.

Phrase of Convenience Phrase of convenience is a term or word used in communication to convey an idea in abstraction. Such phrases can hamper decision making unless the dissonance is filtered out. It is better to avoid phrases of convenience in strategic and tactical matters for brevity and clarity of communication between the parties engaged in transactions.

Proforce Proforce is the converted or reengineered anteforce.

Psychonomics Psychonomics is the study on influence of a conditioned mindset in earning and spending money. Rather it is the attitude of an individual human towards money that reflects his or her ways of earning and spending. It is sometimes called behavioral economics or finance, though not exactly the same. There are many differences. Psychonomics is yet to be studied in detail as an exclusive topic. This study believes psychonomic studies can throw lights on the security paradigm of human needs and wants besides optimization of economic security governance.

Psychological Contract Psychological contract as a term was originally used to explain obligatory relationship between parties in employment relations about their expectations, aspirations, etc. The term is introduced in this study to highlight mutual relationship between a citizen and the nation which is beyond the legality of citizenship, though cannot be separated in exactness. The government or its agencies that represent the nation belong to the other party of the psychological contract. The government is the custodian of the psychological contract of the citizens with the nation

Pyrrhic Victory A Pyrrhic victory is when the victor also becomes vanquished by the loss incurred in the war. Such victory is tantamount to defeat for the victor because of the apocalyptic devastations.

Realistic Idealism Realistic idealism is a concept, posit, or goal that originates from realistic thinking and gradually transforms into realistic stasis under the induced or acquired natural frequency as situations change.

Resource Denial Resource denial is blockading or restricting access to resources to a target human system whether a nation or otherwise. It may be carried out as part of economic warfare, suppression of unlawful activities, competitive strategy, containment, tactics in war, etc.

Resource Ethics Resource ethics in modern world and advanced human system advocates ethical behavior among people and nations for equitable and equal sharing of essential and finite resources for human survival.

Reverse Ethnicity Reverse ethnicity is opposite to forward ethnicity. In reverse ethnicity, humans behave ethnically based on lapsed evolutionary time. It will not be appropriately advanced to the period of their existence. Most of the ethnic crimes could be traced to reverse ethnicity which is even supported by governments.

Revolution in Military Affairs Revolution in military affairs according to this study is a phrase of convenience in strategic affairs that existed in the late 90s. It is a hypothetical approach to war and military theory connected to technological advance and organisational recommendations for reforming and equipping the military for future war as perceived and premised.

Risk Risk is the prospectiveness for a loss under a credulous or astute exposure to danger that will constrain goal achievement. The threat exploits the attractiveness of the target ending up in loss. The exploitation can be natural, accidental, or purposeful. Risk, as a situation, exposes the target credulously to danger.

Risk Etiquette Risk etiquette is the correct way of responding to appreciated risk. Risk etiquette places the decision maker in a dilemma of sorts: whether to face it or not. Decision making under risk follows the risk etiquette appropriate to the situation.

Rule of Law Rule of law in its application to governance is about making and enforcing law correctly in a human system. Governance should ensure it is law that rules the system and not arbitrary and whimsical decisions of those in power.

Sapien Sapien is a term presently attributed to the species *Homo sapiens-sapiens* (the more advanced subspecies of *Homo sapiens*) in short format. In this study, the term sapien is taken to express the present day *Homo sapiens-sapiens*, considering they should be considerably evolved and advanced compared to their primitive cousins. Hence, sapiens will be a better expression of addressing them, though not taxonomically. More so, the evolution is continuing and behavioral changes are visible in modern humans. Another point is that by such upgradation which is purely psychological and not transformational, humans as a species should do well in forward planning for a better life under national security governance meant for people who can reason more intellectually, without waiting

for an evolutionary species change. It will take a long time. Accordingly, the author defines a sapien as *the human form separated from the Homo sapiens-sapiens mold as a first generation intellectually oriented species that stand unequivocally separate from the family of great apes with a dynamic precinct focused on future. Simply put sapien is the human who understands intellect is for the well-being of all in the species and limitations are meant to overcome and not restrict.*

Sapien Human Sapien human is a human capable of moderating his or her survival emotions, unlike standard *Homo sapiens-sapiens*, for collective and cooperative survival and well-being without waiting for forward evolution genetically as a species. A sapien human can be said to be ahead of time using intellectual prowess to appreciate life.

Self-actualization Self-actualization is the process ideated by Abraham Maslow in his theory about the hierarchy of human needs at the apex of the pyramid. But this study considers it as a process which is not pyramidal. Self-actualization is a mental state that occurs in an active human during an activity that makes him or her maximum productive. Self-actualization, therefore, remains a moment of peaking in the concerned activity, a kind of experience as stated by Maslow that motivates a person to perform the activity better and acceptable to the norms of the activity in a realized manner.

Semantic Aberration Semantic aberrations cause constraints in informational security. Information can be distorted by uncared or frustrated communication causing semantic aberrations. Without semantic aberrations, the information becomes knowledge factor in communication and thereby useful for decision making.

Semantic Consensus Semantic consensus is when the sender and receptor are on the same pedestal of appreciation of the term used in communication.

Semantic Dissonance Semantic dissonance occurs when one doesn't get the term used by the other correctly and appreciates it wrongly. There is no consensus. The term, thereby, creates dissonance in the receiver impacting decision making. Semantic dissonance can cause critical problems in governance. It can be natural or deliberate. The parties may be aware or unaware of it.

Sexiquette Sexiquette is the etiquette the partners may follow in healthy sexual interactions with mutual respect irrespective of individual sexitude.

Sexitude Sexitude is the individual attitude towards sex and at the time of sexual interaction with another.

Singularity Singularity is a term used to express the nature of humans and human systems in a singular posture—unidimensional behavior that is applicable to all. It means they, the humans, are singularly identical. It is the organic singularity perspective. Or more technically, human and human systems lap dissolve into a stasis of singularity whether being together or standing separate.

Social Contract Social contract is the relationship between the people and their society. It is similar to group behavior where individuals normally forgo their needs and wants of the time for the overall benefit of the group and thus get

identified with the group. It is the responsibility as well as accountability together of an individual towards the group that he or she belongs to.

Space Maxima Space maxima is a term used in this study for maximizing the space property of a nation including space advantage for national security maximization by governance.

Special Areas Special areas (SA) are declared areas in the sea under the International Convention for the Prevention of Pollution from Ships (MARPOL) in which, for technical reasons relating to their oceanographical and ecological conditions and sea traffic, the adoption of special mandatory methods for the prevention of sea pollution is required. Under MARPOL, they are provided with a higher level of protection than other areas of the sea. There are 778 special areas in the ocean (2020). There can be PSSA within SA and vice versa.

Spiritual Security Spiritual security fills the void between apparent security and perceived security in national security governance. Individual and group humans fill in the gap with activities that will satisfy their perceived security to some extent. Governments cannot provide perceived security directly. They may follow ethical governance to provide perceived security by aligning it indirectly with apparent security. Ethical governance thus becomes part of strategic national security. It is important to understand that spiritual security is not spirituality. But spirituality is one among a host of activities in which humans are always engaged to feel perceived security. Spiritual security manages the deficit in national security.

Stratagem Stratagems are crafted schemes for strategic and tactical maneuvers in national governance for achieving the end objective, the goal of governee—human well-being.

Strategy Strategy is a well and prudently crafted long-term competitive plan to achieve an identified goal in governance.

Subhuman Intelligence Subhuman intelligence is a term that describes reverse application of intelligence in strategic and tactical moves. Subhuman intelligence is intellectual acuity that is in appropriate and inadequate to the period. Primitivism prevails under subhuman intelligence.

Super Power Super power is a nation that has the clout for steering international decisions normally based on military and economic powers. It is not based on national security, but national power that could also turn to be coercive power in the geostrategic context. Nations that hold the polarity of the power axis in the binary axes system possess maximum stasis of super powers.

Super State Super state is ideally a nation that has highly optimized national security status acquired by the total integration of all elements and terrain of national security by astute governance. Superstate is presently a concept under idealistic realism. One of the conditions of a superstate is maximum forward moving national security index. It has to be dynamic. Superstate is not a utopian concept. The superstate is not the apex organ of the hierarchy of nations, but one with them as a model for national security governance. The idea of superstate can turn the human system into a unitary axis in the bipolar system that will not be

based on power or belief systems but human well-being. As in super power status, a superstate can also be replaced. But such replacement will be sans conflicts. Sans conflict is greatly an improbability in a human system being a default mechanism. This topic needs serious study.

Surging Surging in national security parlance is the forward and backward (fore and back) movement of a human system while advancing forward in time. The system will be advanced in evolution, but will reverse in devolution. It is important for a government to maintain the forward momentum of the human system in the advancing mode by carefully observing the surge.

Survival Emotions Survival emotions is a collective term that explains the innate emotions in humans by default that keeps them along the survival track through applications in life. Survival emotions are generated in the neural system without which humans cannot survive in a competitive life scenario. Or rather they cause continuum existence to human life—anger, anxiety, fear, envy, jealousy. Each one of them is expected to fire the urge to survive competitively. They are powerful forces but normally considered negative though vital for existence. That is an incongruent reality of sapien life. More than controlling, containing such emotions is a preferred method for balanced life in a social system.

Symbiotic Interaction Symbiotic interaction is any type of close and long-term interaction between different species under symbiosis. The interaction can be mutualistic, commensalistic, amensalistic, or parasitic.

System A system is a unified, complex, and structural whole of a set of integrated, interactive, and interdependent essentials within a defined boundary. Every system will have a boundary which is important in system identification.

Target Target is the goal, the end objective, in a planned activity.

Terrain Property Terrain property comprises exclusive factors associated with the specific terrain in national security. The objective is to identify and maximize them by national security governance. One of them for any terrain is terrain advantage. While for the land it is the wholesome geoproperty being native to humans, the author had identified ocean property for the ocean comprising ocean advantage, ocean resources, ocean environment, and oceanic islands with respect to a nation's security (Paleri, 2002). In case of the terrains, both geophysical and physical, this study only mentions specific terrain advantage. Other terrain-specific properties have to be identified in course of time by the governments which they may decide to maximize in integrated national security governance.

Terrain Maxima Terrain maxima means maximizing terrain property for national security maximization by governance.

Threat Threat is a cause that generates active probability for a target getting interrupted.

Threat Attraction Threat attraction is target-oriented status that invites threats to it.

Threat Generators Threat generators are the factors that make a target threat attractive.

Threat Negative Threat negative is a term that is used to explain the threat and its parameters that are not yet known. Threat negative is a serious situation in

strategic planning. The goal is a target, and if it exists, the threat also will appear. A target cannot exist without a threat.

Threat Positive Threat positive is a better scenario than threat negative as it means the threat is known and identified.

Trade-off Trade-off is a critical decision factor for any governing system. Trade-off is between two features, where both are not only desirable, but also equally urgent for a human or human system. One is sacrificed for another decisively. It is a situational decision in which a desirous something is discarded or given away deliberately for an assured gain of something else equally desirable. There is loss as well as a gain in a trade-off.

Uncertainty Uncertainty is when there is no knowledge of things that may or may not happen. It is an intellectual limitation and is time functional. Uncertainty is different from threat and risk.

UNCLOS **UNCLOS, also known as Law of the Sea Convention**, is an acronym for the United Nations Convention for the Law of the Sea, 1982. **UNCLOS** became operative since 16 December 1982. The Convention establishes rules governing the ocean and its resources besides providing the framework for the development of a specific area of law of the sea. It is signed by 182 countries and ratified by 168 parties (2021). The United States have signed the Agreement.

Unitary Civilization Unitary civilization is the collective human system where each individual stands intellectually unique and singular, but differentially separate with respect to the time of its usage. The unitary civilization is considered hypothetically in an enveloping and dynamically moving worm tunnel where each human has a time-specific positional stasis laterally ahead or astern of another without obstruction, with opportunities to gain or lose bearing with another along the path of intellectual advancement in life. Every human in a unitary civilization is unique and has distinctive opportunity to move ahead in positive intellectual usage in the hypothetical worm tunnel that moves accordingly in evolution. Unitary civilization, thereby, is a vibrant and dynamic human system appreciation of equal opportunity for people to live as a sapient human. According to the concept of unitary civilization, the clashes in a human system are clashes within the unitary civilization in national security decision making. It is vital to understand this theory for national security governance.

Unlawful Unlawful is a term used to describe and explicate an activity that is not conforming to the accepted law or existing rules.

Votebanking Votebanking is a term used to describe partisan governing by pleasing people who matters and gaining power through illegal and unethical practices in elections including rigging, dead people proxy, misleading voters, preventing voters from reaching the booth, bribing, threatening, coercively denying individual thinking, and a host of other methods based on innovative ideas of subhuman intellect. Votebankers are politicians, political workers, and parties that cheat the public to gain power in electoral systems and types of governments. The term is coined in line with mountebanking in financial defrauding, though not similar.

Wealth Wealth refers to tangible and intangible assets, such as commodities and intellectual property. Wealth is different from money. People get confused with this, especially when they consider the credit side of money.

Well-being Well-being is a mental state of a human being where he or she feels individually and collectively comfortable, safe, secure, and hopeful of a well-assured future. It is the feeling of all-around wellness in living as a citizen of his or her country.

Welfare State Welfare state was a concept ideated in the aftermath of the apocalyptic world wars, suggesting governments to make their citizens survive under free doling. It is redundant today, but the governments still project the welfare state syndrome in the name of the poor to stay in power. The government or the political party associated with it uses public money by doling selectively to people directly or indirectly at the cost of others who are not with them.

Worldwide Resource Web Worldwide resource web is a suggestion to globalize resource generation and resource consumption in equitable proportions to the people that comprise the human system apportioned through nations for their people. It is a hard proposal, but efforts can be made in that direction by governments as a collective system.

Yuck Factor 24 The yuck factor in humans is an interesting behavioral aspect—repugnance or abhorrence towards something. The study of microbiomes gives an opportunity for a relook at the yuck factor. It is a behavior that is not explicitly visible in other life forms. Yuck factor means something that induces a feeling of repugnance, revulsion, or disgust in people even on a casual mention of it. An abhorrent situation causes the yuck factor for the person conditioned by it. Though outwardly harmless, yuck factor can interfere with many things in life. It is already there in religious belief systems, hate generators, various areas of ethnic security matters, food, etc.

Zapping Energy Zapping energy is to regenerate energy from spent energy banking on the law of conservation of energy. It means generation, multiple use, and various other methods that may be possible by erudite technological research and social practices.

Zero Depletion Zero depletion is a target for governing resources. It is used in terms of sustainability of resources. Targeting zero depletion in resource security does not mean retaining the “stock” by refilling as and when consumed by regeneration or alternation. It means keeping resource balance according to future demand in spite of present consumption. It also means renewing resources by regeneration or alternation at future rate. Future in resource security means from the very next moment to eternity, where eternity means the period humans will survive on Earth. It is going to be a very long time.

Zero Hunger Zero hunger is the state where every human gets assured access to food. It is also the goal no 2 of the Sustainable Development Goals of Agenda 2030.
